on drilling cast iron and steel, using a plain radial drill with a 6-ft. arm. The American Tool Works Co. comments on these tests as follows:

> The tabulated cutting speeds for cast iron are in most instances somewhat higher than would be recommended for present day high-speed steel drills. In most cases, especially when drilling through scale, the use of cutting speeds above 100 ft. to 110 ft. per min. are excessive, and necessitate frequent regrinding of the drill. However, when drilling finished surfaces in the better grades of iron, cutting speeds up to 150 ft. per min. often are practicable.
>
> For drilling the average run of commercial cast steel, we have found that cutting speeds in excess of 80 ft. per min. quickly dull the cutting edge of the tool, especially if the material has hard spots. For this class of material, cutting speeds for 70 ft. to 80 ft. per min. will cover average conditions.

## 2. EXPERIMENTS ON DRILLING

**FORCES ACTING ON TWIST DRILLS.**—An extensive series of experiments on the forces acting on twist drills of high-speed steel when operating on cast iron and steel is reported by Dempster Smith and A. Poliakoff, in *Proc.* Inst. M. E., 1909. Abstracted in *Am. Mach.*, May, 1909. Approximate equations derived from the first set of experiments are as follows:

Torque, lb.-ft., $T = (1800\,t + 9)d^2$ for medium cast iron . . . . . . . . . . [3]

$T = (3200\,t + 20)d^2$, for medium steel . . . . . . . . . . . [4]

End thrust, lb. $P = 115{,}000\,t - 200$ for medium cast iron . . . . . . . . . . [5]

$P = 160{,}000\,(d - 0.5)t - 1000$ for medium steel . . . . . . . . [6]

$d$ = diam., $t$ = feed per revolution of drill, both in inches. The steel was of medium hardness, 0.29 C, 0.625 Mn.

A second series of experiments with soft cast iron of combined C., 0.2; graphitic C., 2.9; Si, 1.41; Mn, 0.68; S, 0.035; P, 1.48, and medium steel of C, 0.31; Si, 0.07; Mn, 0.50; S, 0.018; P, 0.033; tensile strength, 72,600 lb. per sq. in., gave results from which were derived the following approximate equations:

Torque, lb.-ft., $T = 740\,d^{1.8}\,t^{0.7}$, or $10\,d^2 + 100\,t(14\,d^2 + 3)$ for cast iron . . . [7]

$T = 1640\,d^{1.8}\,t^{0.7}$, or $28\,d^2(1 + 100\,t)$ for medium steel . . . . . [8]

End thrust, lb., $P = 35{,}500\,d^{0.7}\,t^{0.75}$, or $200\,d + 10{,}000\,t$ for cast iron . . . . . . [9]

$P = 35{,}500\,d^{0.7}\,t^{0.6}$, or $750\,d + 1000\,t(75\,d + 50)$ for medium steel, [10]

and for different sizes of drill the equations given in Table 6.

The tests were made without lubricants. When lubricants were used in drilling steel the average torque varied from 72%, with 1/400 in. feed, to 92%, with 1/35 in. feed, of that obtained when operating dry. The thrust for soft, medium and hard steel is 26%, 37% and 12%, respectively, less than when operating dry, no marked difference being found, as in the torque, with different feeds. The horsepower varies as $t^{0.7}$ and as $d^{0.8}$ for a given drill and speed. The torque and horsepower when drilling medium steel is about 2.1 times that required for cast iron with the same drill speed and feed. The horsepower per cu. in. of metal removed is inversely proportional to $d^{0.2}\,t^{0.3}$, and is independent of the revolutions.

While the chisel point of the drill scarcely affects the torque it is accountable for about 20% of the thrust. Tests made with a preliminary hole drilled before the main drill was used to enlarge the hole showed that the work required to drill a hole where only one drill is used is greater than that required to drill the hole in two operations, with drills of different diameter.

**Table 6.—Equations for Various Sizes of Drill**

| Drill | 3/4 | 1 | 1 1/2 |
|---|---|---|---|
| Cast iron $T$ = | 5 + 1,100 $t$ | 10 + 1.750 $t$ | 25 + 3,700 $t$ |
| Cast iron $P$ = | 125 + 82,000 $t$ | 200 + 89,000 $t$ | 350 + 103,000 $t$ |
| Steel $T$ = | 7.5 + 3,350 $t$ | 17.5 + 4,400 $t$ | 40 + 9,000 $t$ |
| Steel $P$ = | 550 + 109,000 $t$ | 750 + 131,000 $t$ | 1,250 + 162,000 $t$ |
| Drill | 2 | 2 1/2 | 3 |
| Cast iron $T$ = | 40 + 5,900 $t$ | 60 + 8,800 $t$ | 90 + 12,900 $t$ |
| Cast iron $P$ = | 500 + 110,000 $t$ | 600 + 126,000 $t$ | 850 + 140,000 $t$ |
| Steel $T$ = | 75 + 12,500 $t$ | 112.5 + 19,050 $t$ | 175 + 26,250 $t$ |
| Steel $P$ = | 1,500 + 181,250 $t$ | 1,725 + 224,375 $t$ | 2,350 + 280,000 $t$ |

**TORQUE AND THRUST IN RELATION TO CUTTING FLUID.**—A research to determine the performance of cutting fluids in drilling is reported by O. W. Boston and C. J. Oxford in *Trans.* A.S.M.E., RP 55–1, 1933 and RP 58–2, 1936. The former relates to drills ranging from 1/2 in. to 1 1/2 in. diameter, and the latter drills from 1/8 in. to 1/2 in. diameter. The materials on which the research was made were as follows: Chilled cast aluminum alloy S.A.E. 33, Brinell hardness No. 70; leaded free-cutting brass, extruded and drawn, of analysis Cu, 61.75, Zn, 35.0, Pb, 3.21, Fe, 0.04, Brinell hardness No. 179; cast iron containing 3.44 C, 2.62 Si, 0.986 Ni, and 0.478 Mn, Brinell hardness No. 179; malleable cast iron containing 2.46 C, 0.26 Mn, 0.163 P, 0.071 S, and 1.00 Si, Brinell hardness No. 137; S.A.E. 3150 steel, annealed, Brinell hardness No. 196; S.A.E. 1020 steel, annealed, Brinell hardness No. 131; S.A.E. 1035 steel, annealed, Brinell hardness No. 156; carbon tool steel, annealed, Brinell hardness No. 152; S.A.E. 1112 steel, cold drawn, Brinell hardness No. 217; The characteristics of the cutting fluids are given in Table 7.

The characteristics of the drills used in the first series of tests are given in Table 8. The smaller drills, from 1/8 to 1/2 in. diameter, all had helix angles of 30 deg. and ratios of web thickness to diameter of 0.185. Point angle was 120 deg., peripheral-edge angle, 130 deg., and clearance angle at periphery was 6 deg.

**Torque and Thrust Formulas.**—The experiments indicated that the torque required for drilling all metals could be expressed by an equation of the form

$$T = Cf^m d^n \quad \ldots\ldots\ldots\ldots \quad [11]$$

where $T$ = torque developed by drill, ft.-lb.; $f$ = feed of drill, in. per revolution; $d$ = diam. of drill, in.; $C$ = a constant depending on material drilled, cutting fluid and the drills. The values of the exponents $m$ and $n$ vary with the material cut and are given in Table 9. Values of $C$ are given in Table 10.

The research established that the values of exponents $m$ and $n$ were identical for all of the steels investigated, and the torque equation for steels, therefore, becomes

$$T = Cf^{0.78}\,d^{1.8} \quad \ldots\ldots\ldots\ldots \quad [12]$$

The thrust equation takes two forms depending on the material drilled. For aluminum and brass it takes the form

$$B = Kf^p\,d^r \quad \ldots\ldots\ldots\ldots \quad [13]$$

For steel and iron it takes the form

$$B = Kf^p\,\{(d/5) + (w/d)\}^r \quad \ldots\ldots\ldots\ldots \quad [14]$$

$B$ = thrust, lb. $K$ = a constant corresponding to $C$ in the torque equation; $w$ = web thickness, in. Values of $p$ and $r$ are given in Table 9. Values of $K$ are given in Table 10.

The research established that the values of exponents $p$ and $r$ were identical for all of the steels investigated, and the thrust equation for steels, therefore, becomes

$$B = Kf^{0.87}\{(d/5) + (w/d)\}^{2.12} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [15]$$

**Tests on Small Drills.**—The tests on small drills showed that the torque equation for all steels was the same as for large drills, that is, it is identical with the equation [12]. The torque equation for other materials with small drills is identical in form with equation [11], but the value of exponents $m$ and $n$ vary as follows:

| | Al Alloy S.A.E. 33 | Leaded Brass | Cast Iron | Malleable Cast Iron |
|---|---|---|---|---|
| $m =$ | 0.83 | 0.83 | 0.69 | 0.78 |
| $n =$ | 1.9 | 1.9 | 1.7 | 1.8 |

The equation for thrust, with small drills, is of the same form as equation [13], the exponent $r$ in all cases being 1, with the exception of aluminum alloy, in which case $r = 1.2$. The value of the exponent $p$ for all of the steels is 0.87. Its value for the other materials is as follows:

| | Al Alloy, S.A.E. 33 | Leaded Brass | Cast Iron | Malleable Cast Iron |
|---|---|---|---|---|
| $p =$ | 1.0 | 0.6 | 0.73 | 0.75 |

Values for constants $C$ and $K$ in the torque and thrust equations are as follows:

| | Al Alloy S.A.E. 33 | Leaded Brass | Cast Iron | Mall. Cast Iron | Steel | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | | | | S.A.E. 3150 | S.A.E. 1020 | S.A.E. 1035 | Carbon Tool | S.A.E. 1112 |
| $C =$ | 556 | 512 | 347 | 689 | 1,500 | 1,740 | 1,300 | 1,842 | 1,000 |
| $K =$ | 90,400 | 6160 | 25,800 | 24,400 | 104,300 | 96,000 | 133,100 | 108,500 | 74,100 |

The effect of thinning the point of drills was to materially decrease the thrust. Values of thrust may be lowered as much as 50% by point thinning. Both torque and thrust decrease with an increase of helix angle, both being reduced a total of 26% as helix angle is increased from 21° 26′ to 40° 23′. This probably is due to relatively easier escape of chips from the flutes. However, the life of the drill with the largest helix angle is considerably below the life with the smaller helix angle. The influence of web thickness on torque and thrust is negligible with feeds up to 0.004 in. For heavier feeds, torque increases rapidly, probably because of the decreased cross-sectional areas of the flutes, causing increased frictional resistance to the flow of chips. Experiments with drills 1 in. diameter, however, show constant torque for drills with different web thicknesses.

**Effect of Cutting Fluids.**—The research showed that savings were possible with cutting fluids, as compared with dry drilling. Taking the net power output for drilling dry, as 100%, savings were shown as follows: Aluminum alloy S.A.E. 33, 90% mineral oil and 10% lard oil, 31.7%; leaded brass, none; cast iron, mineral oil, with 5% oleic acid, 17.2%; malleable cast iron, lard, mineral, compounded or sulphurized oil, 10.5%; S.A.E. 3150 steel, sulphurized mineral oil, 23.0%; S.A.E. 1020 steel, sulphurized oil, 33.3%; S.A.E. 1035 steel, sulphurized lard-mineral oil, 26.0%; carbon tool steel, sulphurized mineral oil, 21%; S.A.E. 1112 steel, sulphurized lard-mineral oil, 6.8%.

Discussing the paper, Alvan Davis, *Trans.* A.S.M.E. RP 55–1, p. 25, 1933, stated that there is no gain in using cutting fluid with free-cutting brass at the speeds used in the Boston-Oxford experiments. However, in automatic machine operations, speeds of about five times those reported in the paper are used, and a copious supply of light paraffin oil is necessary to prevent the drills from burning up.

# PRESSURE WORKING OF METALS

By H. B. Morse

## 1. PLASTIC PROPERTIES OF METAL

**THE PLASTIC WORKING** of metal requires the use of powerful machines to change the shape, contour or cross-section of the initial shape by force as compared with change of shape by the whittling operations of machine tools. The theory involved applies not only to mechanical and hydraulic press operations but also to hammer work, rolling operations, bench and wire drawing, spinning and shearing.

**HOT AND COLD OPERATIONS** are to be found under almost all of these headings. The obvious distinction is whether the metal is to be heated preparatory to working or whether it is to be worked at room temperature. Another worth-while distinction is the relation of working temperature to the recrystallization temperature, or range of temperatures.

**Above the Recrystallization Range** the metal movement seems to be largely inter-crystalline. Any (transcrystalline) slip-plane distortion through the crystal is corrected at once by what has been termed *spontaneous annealing*, and the crystal structure is unstrained upon completion of the operation. At elevated temperatures the amount of work performed on the metal is practically unlimited except by the capacity of the part to "hold the heat." Working loads increase with speed of working in the lower speed ranges, but most production operations seem to be above this range and are affected very little by changes of speed. It should be noted that tin and lead are above their recrystallization range at normal room temperatures and work at such temperatures in the same way that steel and brass work at elevated temperatures. Zinc is in its hot working range at about 300° F.

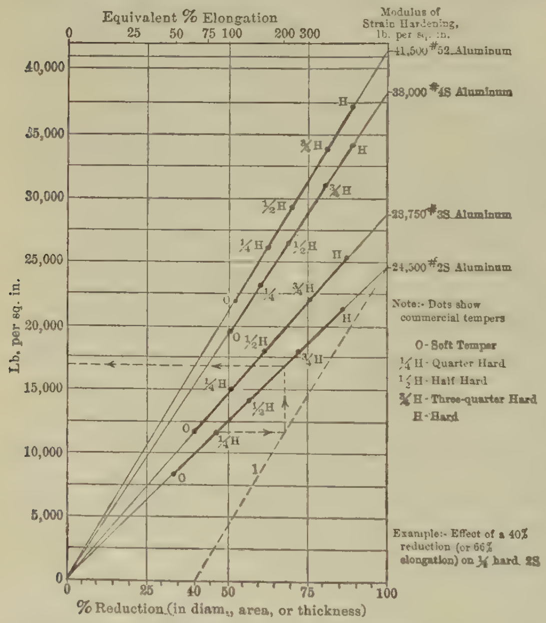

Fig. 1. Plastic Range Chart for Four Grades of Aluminum at Room Temperature

**COLD WORKING** of metals (below their recrystallization temperatures) causes cumulative strain-hardening with a progressively increasing yield point, due to slip-plane movements to the individual crystal. After severe strain-hardening in one or a series of operations the metal must be annealed to restore an unstrained crystal structure before further cold working can be undertaken.

**ANNEALING** requires sufficient temperature to enable the atoms of the distorted structure to gain sufficient kinetic energy to rotate themselves into their normal space lattice relation, in the formation of new and unstrained crystals. This is recrystallization, and occurs at somewhat lower temperatures in the more severely worked metals. The new small crystals (or grains) increase in size with increasing temperature or continued application of heat until they reach the desired size. Plasticity improves and yield point becomes lower as grain size increases, but excessive grain size results in dangerous non-uniformity. In annealing low carbon steels (0.02 C–0.12 C) it is necessary to heat quickly to a point above the *germination temperature*. Germination is an excessive and sudden grain growth occurring at suitable combinations of strain and temperature. A non-uniformly strained stamping is likely to include some local area of favorable strain, and if germination occurs the local large grains will result in an area of weakness.

**THE PLASTIC RANGE** (See Figs. 1 and 2) for the cold working of metals lies between the initial yield point in the commercially annealed state, usually designated as soft temper, and the severely strain-hardened state in which all conveniently oriented slip-planes have been used up so that internal fractures are likely.

**THE PLASTIC CYCLE** includes strain-hardening by cold working and then restoration to the unstrained state by annealing. This cycle may be repeated many times in fabricating the common metals.

**THE APPLICATION OF STRAIN-HARDENING THEORY,** Fig. 1, permits: Adding the effect of a series of cold-working operations; judging the need for annealing; finding the yield point or resistance developed in an operation, for figuring equipment required. An example in dotted lines is arranged with arrows to show the method of using the chart. The plastic range for each metal is indicated by a heavy line and the standard aluminum tempers (listed beside Fig. 1) are indicated in order by dots. There is still a shortage of consistent test data relative to the plastic range properties of metals, but the selection of tentative values given in Table 1 and Figs. 1 and 2, has been made with considerable care.

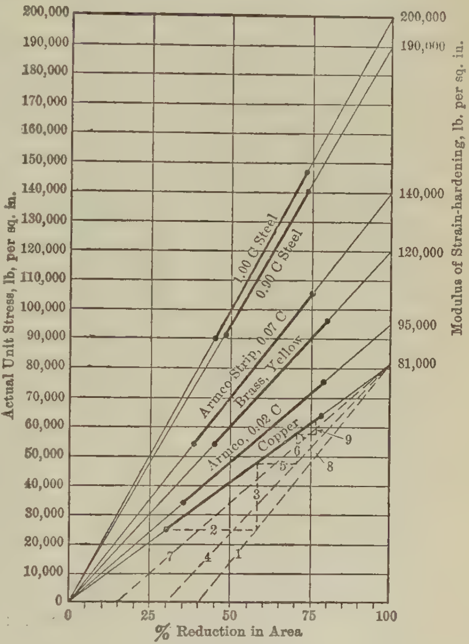

FIG. 2. Strain-Hardening Curves

EXAMPLE 1.—A reduction of 40% is to be made on 2S Aluminum 1/4 H. On Fig. 1, first draw a line from the modulus of elasticity of 2S Aluminum (24,500), to 40% on the base line. Then draw a line horizontally from the initial state (1/4 H) across to line 1. Then draw a line vertically upward to a point representing completion of the work on the plastic curve. A horizontal line drawn from this point back to the unit stress line shows about 16,500 lb. per sq. in. yield point reduction.

EXAMPLE 2.—Determine the cumulative strain-hardening effect of a series of operations on copper, and check approximately whether or not an annealing operation is required. It is assumed that copper is received in the soft temper or commercially annealed state and that the operations to be performed, involve successive reductions of 40, 30 and 50%. (See Fig. 2.) The construction lines are numbered in order, and indicate successive yield points as follows: Before the first operation, about 25,000 lb. per sq. in.; after the first operation, about 42,000 lb. per sq. in.; after the second operation, about 51,000 lb. per sq. in.; after the third operation, about 62,000 lb. per sq. in. The final point is still within the plastic range of the material so that an annealing operation has not yet been required. It is obvious however that the material is now severely strain-hardened and must be annealed before any further working is possible.

## 2. EQUIPMENT

**METAL WORKING EQUIPMENT** is most easily discussed by comparing several groups according to their structural characteristics rather than their applications. This particularly is true because applications often overlap.

**THE HAMMER GROUP** (See also pp. 19–03 to 19–22) is the oldest, tracing directly to the swinging sledge in the hands of the early blacksmith. In each case the principle is essentially the same; the job absorbs at each blow the whole energy of the hammer head. One, several, or many blows may be required to complete the part. As most types of hammers

† Tensile.

‡ Compression. § Below room temperature. ¶ Room temperature.

employ a gravity fall, the energy delivered to do work at each stroke is the product of the weight of the hammer head multiplied by the distance through which it falls. In some cases the velocity of the head is increased mechanically and its energy must be derived from its weight and its velocity as it reaches the work.

**Helve Hammers, Steam Hammers and Air Hammers** may fall in either of the above classes. They usually are used for simple forging and taper drawing operations with plain-faced hammer heads and anvils.

**Board-lift Drop Hammers** are still widely used for forging operations which require dies with several developed shapes in them to preform and finish-form the required part. The hammer usually is rated by the weight of the head in pounds.

**Belt-lift Hammers and Rope-lift Hammers** usually are used for single die work. The belt-lift hammers developed for the jewelry trade, had a belt attached to the slide and carried up over a constantly revolving drum. Pulling on this belt gave it enough traction on the pulley to lift the slide. The rope-lift drop hammers followed a similar principle except that the head was very heavy and large in area and was lifted by double ropes wrapped two or three times around the drum for better lifting traction when tightened.

**ROTARY SWAGING MACHINES** for tapering, pointing and reducing tubes and rods, resemble helve hammers in accomplishing their results by many quick blows. The blows are delivered, however, by a group of cam-actuated rolls revolving around the work.

**PERCUSSION PRESSES,** or power screw presses, are an intermediate development between the drop-hammer and power-press. The slide is driven up and down by a large steep-pitch screw, traveling up through a fixed nut in the frame to a light fly-wheel on top. Friction contact of the fly-wheel rim with a constantly revolving disc on one side drives the slide down at increasing velocity until the die comes in contact with the work and all the energy of the fly-wheel is absorbed. Then another revolving disc makes contact with the other edge of the wheel and lifts the slide. Foot treadle control, similar to that of a drop hammer, is used.

**HYDRAULIC PRESSES** come after hammers in development, but occupy a rather different field. Essentially slow-moving machines, due to fluid friction and inertia of long columns of liquid and of accumulators, they were limited to hot-forming operations on parts heavy enough to hold heat over a considerable time, and to cold operations on limited production. Subsequent developments have increased their speed materially at the expense of some complication by introducing variable-delivery motorized pumps, gravity fill systems and foot valve controls. Fast-acting hydraulic presses are adapted to some production metal-working operations, both hot and cold, particularly where it is important to limit the working loads. The operations include particularly heavy forging, hot extrusion of shells and shapes, heavy bending and cold flattening.

**MECHANICAL POWER PRESSES** and such modifications as headers, upsetting machines, bulldozers, bending brakes and (boiler) punches, comprise essentially: A substantial frame, a reciprocating slide with actuating crank-shaft, a clutch for control and a fly-wheel. This fly-wheel is the important distinction from previous types of machines, in that it permits large energy storage during the idle period of each cycle and practically instant delivery of the energy required during the brief working period. Many variations of press design are possible in size, shape and position of frame, type of clutch and use of gearing. Accessories include knockouts, blank-holding devices and other clamping means, and mechanical feeds of many types.

**PRESS POSITION** is one of the most important design modifications. The upright position is the most common, with the slide descending vertically to perform the work. A considerable proportion of the smaller sizes are made *inclinable*, so that they may be used in the upright position or inclined as much as 30 or 40 deg. at will, to facilitate gravity discharge of the work. This same consideration is responsible for many specialized and single-purpose machines being inclined at greater angles (45, 60, 75 deg.) and an even larger group being mounted horizontally. The latter group includes nail machines, forging machines, special purpose headers, some redrawing presses, bulldozers, etc.

**OTHER DESIGN FEATURES.**—Pressure may be delivered from crank- or eccentric-shafts to the work slides; through one central connection (as in single-crank presses), or through two connections (double-crank presses), or through four connections at the corners of the slide. For extremely short strokes and high pressures, the crank-shaft is moved to one side and used to straighten a pair of knuckles or toggles to obtain high mechanical advantage. The energy-storing fly-wheel usually is mounted directly on the crank-shaft for relatively fast and easy jobs. Gearing is introduced between the fly-wheel and the crank-shaft, as the energy demand and stroke increase, to speed up the wheel and to keep down the tool operating speed. Single gear reductions, up to about 7 $^1/_2$ : 1, suffice on small and moderate size presses. The larger presses usually require double gearing. Twin driving gears at each end of the crank-shaft, to divide the torsional driving strain, become advisable for extreme strokes (say 2 or 3 times the shaft diameter). Positive engagement clutches between the crank-shaft and driving wheel, are widely used on the smaller presses which may be turned over by hand for die setting purposes, with fair ease. Friction clutches on the back-shaft are preferred on large presses to facilitate die setting.

**DRAWING OPERATIONS** in power presses require added motions for blank-holding purposes. The common single-action presses may be fitted for the easier drawing operations by adding spring or rubber pressure attachments or by using pneumatic die cushions which give better results and are more convenient. For the more severe draws, shallow stretching, and for power economy, double-action presses are used. These have the crank-actuated drawing slide or plunger, and around it an outside slide which is forced down rigidly to hold the blank, by means of cams in the early models, and now by a system of toggle linkages. A further modification known as "triple-action" equipment permits combined drawing and redrawing at one handling.

**SHEARS.**—Squaring shears or "gate" shears are essentially a single-purpose modification of the gap frame double-crank type of power press, arranged with a pair of shear blades, a hold-down to clamp the metal while cutting it and a set of gages to assist in locating the cut. Circle-cutting shears, rotary slitting shears and gang slitting machines for two or more parallel cuts, all belong to the next group.

**ROLLING ACTION** characterizes a large group of metal-working machinery and distinguishes it from all of the foregoing *reciprocating action* machines. Working pressures in all cases must exceed the yield point of the metal in whatever state received; hot or cold, annealed or strain-hardened. In the rolling machines the working pressure is localized on a very small area at the point or line of contact between the rolls and the work. In most cases, except oscillating forging rolls, the work is progressive and a continuous and more or less uniform supply of power must be maintained.

**ROLLING MILLS** are used for the initial reduction of a hot mass of cast metal, and for subsequent hot and cold operations in the production of plate, sheet, strip and various rolled shapes. For shapes (rails, beams, etc.) a series of grooves in the rolls must be worked out to develop the desired shape from an initially rectangular section. For light-gage cold rolling, small diameter work rolls may be used to reduce the contact area and load relative to the reduction per pass. These work rolls should be backed up by larger diameter rolls to minimize deflection and maintain uniformity of gage. For large production, trains of several stands of mills in series are used to perform consecutive rolling operations at one pass.

**PROGRESSIVE FORGE ROLLING** is a modification of shape rolling, to compete with large-quantity drop forging. In this process matching impressions of the desired forging are cut at intervals in the surfaces of a pair of mill rolls of suitable diameter. The forgings are trimmed out of each bar of flash at the mill. Related to this process by antedating it, *oscillating forging rolls* with a single pair of impressions have been used particularly for suitable shapes in the production of agricultural implements.

**PROGRESSIVE ROLL FORMING MACHINES** use several pairs of suitably shaped rolls to convert metal from flat strip or coil form to a variety of shapes such as molding, channel, lock-seamed tubing, etc.

**SPINNING LATHES** are used for surface burnishing, trimming and curling of some cooking utensils and for spinning wrinkles out of some taper jobs. They also are used to spin flat blanks or plain drawn shells to various shapes on wooden or metal chucks. The working area on a spinning operation usually is little more than a point contact against the spinning roll or hand tool.

**BEADING, FLANGING, THREAD ROLLING, KNURLING, CURLING, DOUBLE SEAMING** and other rotary cold-forming operations are performed in a variety of ma-

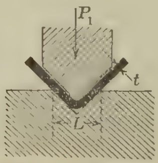

FIG. 4. Bending in V-Dies

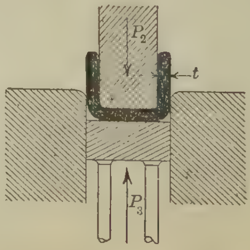

FIG. 5. Bending in U-Dies

chines from simple parallel-shaft, hand-served types, to multiple-spindle, chute-feed, high-speed automatics.

**PROFILE DIES,** to suit the cross-section of the required product, characterize a group of machines including wire blocks, draw benches and hydraulic extrusion presses.

**WIRE DRAWING** employs power-driven capstans or drums to pull the wire through reducing dies, which have much in common with dies for ironing cartridge case walls and other drawn shells.

**DRAW BENCHES** employ a capstan, chain and clamp to pull cold strip metal through proper die slots to change its shape to that of a molding or other progressively bent job. Horizontal hydraulic extrusion presses may be arranged for rather similar work, except that they achieve their results by pushing hot material through a suitably shaped die opening.

## 3. SELECTION OF EQUIPMENT

**FORMULAS** for use in the selection of the foregoing equipment to suit particular job requirements are given below. They are kept as simple as possible, and necessarily omit some more or less intangible factors for which a factor of personal judgment should be added in practically all cases. It would be foolish to try to use more complicated formulas to avoid some small error when the materials to be worked are subject to as wide variations in physical properties as is found to be unavoidable.

**HAMMERS.**—For data governing the selection of hammers, see pp. 19–03 to 19–22.

**TRIMMING PRESS** sizes which have been found suitable for use with drop hammers under average conditions are given in Table 2.

**Table 2.—Trimming Press Sizes**

(E. W. Bliss Co., Brooklyn, N. Y.)

| Drop-hammer ram weight, lb | 600 | 800 | 1000 | 1200 | 1500 | 2000 | 2500 | 3000 | 5000 | 8000 |
|---|---|---|---|---|---|---|---|---|---|---|
| Trimming press, shaft diameter, in | 3 1/2 | 4 | 4 1/2 | 5 | 5 1/2 | 6 | 6 1/2 | 7 | 8 | 9 |

**ROLLING OPERATIONS.**—The working or contact area between the rolls may be taken as:

$$A = w\sqrt{R \times (t_1 - t_2)} \qquad [1]$$

where $t_1$, $t_2$ = respectively thickness of strip entering and leaving the rolls, in.; $R$ = radius of roll, in.; $w$ = width of strip, in.

The working or screw-down pressure then will be

$$P = C \times S \times A \qquad [2]$$

where $S$ = yield point of the metal at that particular stage in the rolling process; refer to the strain-hardening curves, Figs. 1 and 2. $C$ = 1.3 may be taken for soft temper and relatively heavy gage material up to 3.8 for light-gage and strain-hardened work, to cover both the elastic deformation of the rolls and the pyramiding of the pressure due to constriction of flow in the working area. For further information also see bulletin entitled Rolling-Mill Data for Calculation and Design, issued by S. K. F. Industries, Inc., Philadelphia, Pa.

**BENDING.**—The length of strip or bar, $L$ in Fig. 3, to be allowed for making bends, when cutting blanks, depends on the inside radius $r$, the angle of the bend $\beta$, and the thickness of the metal $t$. The allowance $L$ is not a true arc at a distance $^1/_2\ t$ from the die radius. A true arc is close enough for calculations, however, if it is taken at a radius of $(r + 0.4\,t)$. Then

$$L = (r + 0.4\,t) \times (2\pi\beta/360) \qquad [3]$$

$$\text{Total length of blank} = X + L_1 + Y + L_2 + Z \qquad [4]$$

**BENDING PRESSURE FOR V-DIES.**—See Fig. 4. Let $S$ = ultimate tensile strength of the metal, lb. per sq. in.; $L$ = span of female die, in.; $w$ = width of strip, in.; $t$ = thickness of strip, in. Then, bending pressure $P_1$, in pounds, is

$$P_1 = (C \times S \times w \times t^2)/L. \qquad [5]$$

$C$ = 1.33 when $L = 8t$; = 1.24 when $L = 12t$; = 1.2 when $L = 16t$. If the punch is set down hard to squeeze the surface metal and cause balancing strains in order to minimize "spring-back," the load will be higher than for bending only. In such a case, the job should be considered as coining, and the contact area should be reduced to suit.

**BENDING IN U-DIES.**—See Fig. 5. The bending pressure $P_2$ on the punch will be

$$P_2 = {}^2/_3\, S \times w \times t \times (1 + t/L) \qquad [6]$$

and the pressure $P_3$ required on the pad to hold the bottom from bowing will be

$$P_3 = {}^2/_3\, (S \times w \times t^2)/L \qquad [7]$$

Notation for equations [6] and [7] is the same as for equation [5].

**BENDING IN ROLLS.**—The screw-down pressure $P$, in pounds, may be approximated from

$$P = 12 \times \Delta \times E_m \times w \times t^3, \quad \ldots\ldots \quad [8]$$

where $\Delta$ = deflection, in.; $E_m$ = modulus of elasticity; other notation as before.

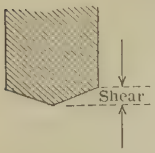

Fig. 6. Shear on Punches

**BLANKING, PIERCING OR SHEARING** with flat tools. Pressure $P_1$, in pounds, for rectangular work is given by

$$P_1 = L \times t \times S \quad \ldots\ldots\ldots\ldots \quad [9]$$

For round work, the equation becomes

$$P_1 = \pi \times D \times t \times S \quad \ldots\ldots\ldots \quad [10]$$

where $S$ = shearing strength of the metal (Table 1); $L$ = total length or periphery of the shearing cut, in.; $t$ = thickness of metal, in.

**BLANKING WITH SHEARED TOOLS.**—Pressure required $P_2$, in pounds, is given by

$$P_2 = (P_1 \times t \times p)/s \quad \ldots\ldots\ldots\ldots \quad [11]$$

where $p$ = penetration, percent; $s$ = shear, in. (see Fig. 6); $t$ = thickness of metal, in. $P_1$ is obtained by equation [10] and values of $p$ may be taken from Table 1.

**WORK IN BLANKING.**—Let $W_e$ = working energy = (working pressure × working distance), usually in inch-tons. Then

$$W_e = (t \times p \times P_1)/2000 \quad \ldots\ldots\ldots\ldots \quad [12]$$

Notation is the same as in equation [11]. Sufficient clearance for clean fracture is assumed and no allowance is made for friction losses.

**BLANK DIAMETERS FOR DRAWING SHELLS.**—Let $D$ = blank diameter, in.; $d$ = mean shell diam., in.; $h$ = height of shell, in. Then

$$D = \sqrt{d^2 + 4\,d\,h} \quad \ldots\ldots\ldots\ldots \quad [13]$$

Refer also to the wide range given in Table 3.

**LOADS IN LIMIT DRAWS.**—The load in a limit draw is the force $P$, pounds, necessary to push the bottom out of the shell being drawn. If $L$ = length of perimeter, in.; $t$ = thickness of metal, in.; $S$ = ultimate tensile strength of the metal (Table 1),

$$P = L \times t \times S \quad \ldots\ldots\ldots\ldots \quad [14]$$

For round work this equation becomes

$$P = \pi \times d \times t \times S \quad \ldots\ldots\ldots\ldots \quad [15]$$

where $d$ = mean diameter of shell, in.

**LOADS IN SHALLOW DRAWS.**—The load in a shallow draw (blank diam. = $D$) is

$$P = \pi \times d \times t \times S \times \{(D/d) - 1 + C\} \quad \ldots\ldots\ldots \quad [16]$$

in which notation is the same as for equation [15], and the constant $C$ = 0.3.

**LOADS IN DRAWING RECTANGULAR SHAPES.**—

$$P = t \times S \times \{2\,\pi\,r\,C_1 + (L \times C_2)\} \quad \ldots\ldots\ldots \quad [17]$$

where $r$ = corner radius of rectangular shell, in.; $t$ = thickness of metal, in.; $S$ = nominal ultimate tensile strength of the metal (see Table 1); $L$ = total length of the straight sides of the shell, in.; $C_1$ = 0.5 for a very low shell, up to, say, 2 for a shell of a depth of five or six times the corner radius $r$; $C_2$ = 0.2 for easy draw radius, ample clearance and no holding pressure, or, say, 0.3 for similar free flow and a normal blank holding pressure of about $^1/_3$ $P$, or a maximum of 1 with the metal clamped too tightly to flow.

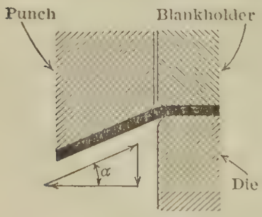

Fig. 7. Loads in Shallow Stretching

**LOADS IN STRETCHING** or shallow forming operations, in which the metal is gripped tightly around the edge, are determined by

$$P = L\,t\,S_e \sin\alpha \quad \ldots\ldots\ldots \quad [18]$$

where $P$ = punch pressure, lb.; $L$ = punch periphery, in.; $S_e$ = elastic limit or yield point of metal, lb. per sq. in. (see Table 1). $\alpha$ = angle of incidence (see Fig. 7).

**REDUCTIONS PER DRAW.**—In drawing round shells, the following figures can be used for first reductions:

| | | | | | |
|---|---|---|---|---|---|
| Percent reduction in first draw, $(D - d)/d$...... | 30 | 35 | 40 | 45 | 47.5 |
| Approx. min. blank thickness, percent of its diameter, $(t/D)$ | | | | | |
| Double-action.......................... | 0.15 | 0.2 | 0.3 | 0.4 | 0.5 |
| Single-action.......................... | .. | 1.5 | 1.7 | 2.0 | 2.5 |

The reductions in succeeding operations are as follows: For each succeeding double-action operation, a 30% reduction is the common limit. For each succeeding single-action operation, a 25% reduction is the normal maximum, although reductions as high as 37% have been recorded with heavy metal and two-step dies.

**RULE FOR DEPTH OF DRAW FOR RECTANGULAR SHELLS.**—In drawing rectangular shells, the limit depth per operation is about four to six times the corner radius, because of distribution of surplus metal from the corner area into the adjacent wall area.

**BLANK-HOLDING PRESSURES.—Rectangular Shells.**—For large rectangular work the drawing pressure is relatively lower than for round work, but the allowance for blank-holding may run as high as 100% of the drawing pressure.

**Shallow Stretching Work.**—In stretching shallow shapes the metal must be gripped tightly around the edge, and blank-holding pressure may be as high as two or three times the relatively low drawing pressure.

**Round Shells.**—The pressure required to hold the blank flat while deep drawing round work varies from zero in case of relatively thick blanks, up to about $^1/_3$ or $^1/_2$ of the drawing pressure. When the blank-holding pressure exceeds $^1/_3$ of the drawing pressure it is best to use draw beads to permit the blank-holding pressure to be decreased. Tapered or domed shapes must be classed with shallow stretching above.

**BLANK-HOLDING DEVICES.**—Mechanical grip on the edges of the blank, as obtained in toggle and cam presses, is, for practical purposes, positive and non-yielding. It is particularly desirable for domed and tapered shallow shapes and for shallow stretching, especially where draw beads must be stamped to help grip the metal.

Rubber bumper pressures may be approximated at 10 lb. per sq. in. of area, per 1% of compression. Actually, by test, the pressure rises on a slightly accelerating curve, and varies with the composition, temperature and age of the rubber. (See pp. 5–27 to 5–31.) Spring pressures may be figured from spring tables elsewhere in this book. (See pp. 10–03 to 10–22.) More uniform pressures and more convenient control of pressure, are obtained with die cushions. Pneumatic die cushions may be selected on a basis of 100 lb. per sq. in. of piston area, maximum; and hydro-pneumatic cushions for drawing purposes, on a basis of about 500 lb. per sq. in.

**REDUCTION PER ANNEAL.**—The total percent reduction accomplished between annealing operations, whether in one or more operations, should be kept within the "percent reduction in area" found in tensile tests of the annealed material (Table 1).

**WORK DONE IN DRAWING OPERATIONS.**—Let $W_e$ = working energy, in.-tons = (working pressure × working distance); $P$ = drawing pressure, tons, plus blank-holding pressure in cases of spring, rubber or air drawing attachments; $h$ = shell height, in.; $C$ = constant = 0.60 to 0.80 to allow for the gradual rise of pressure; Then

$$W_e = P \times h \times C \qquad [19]$$

No allowance is made for friction losses.

**SQUEEZING OPERATIONS.**—The load $P$, lb., in squeezing operations is

$$P = A \times S \qquad [20]$$

where $A$ = projected area, sq. in., of the surface of a job and flash which is in contact at the completion of the squeeze; $S$ = compressive stress, lb. per sq. in. (see Table 1).

**Work Done in Squeezing** is

$$W_e = P \times l \qquad [21]$$

where $P$ = average pressure, tons; $l$ = working distance, in.

In figuring work in squeezing operations the distance the punch travels, from its first contact with the slug or blank to bottom of stroke, includes the amount the metal is moved and the amount of deflection in the press and tools. The working pressure initially is the yield point of the metal *times* the initial area of contact. It will rise gradually as the material strain-hardens and the contact area *increases*. In the case of closed dies there is likely to be a further sharp rise when the die fills, its duration and extent being determined by the amount necessary to stretch the press to get over bottom center. The metal practically is incompressible.

**UPSETTING RULES.**—1. The limit of length of unsupported stock that can be gathered or upset in one blow, without injurious buckling, is not more than three times the diameter of the bar. 2. Lengths of stock more than three times the diameter of the bar can be upset successfully in one blow (in a closed die), provided the diameter of the upset made is not more than one and one-half times the diameter of the bar. 3. In an upset which requires more than three diameters of stock in length, and in which the diameter of the upset is one and one-half times the diameter of the bar, the amount of unsupported stock beyond the face of the die must not exceed one diameter of the stock.

**BULK MODULUS** $B$ in Table 1 is of use in determining the elastic change of volume under a stress $S$, lb. per sq. in. If $V_1$, $V_2$ = respectively, larger and smaller volumes,

$$(V_1 - V_2) = (S \times V_2)/B \quad \text{. . . . . . . . . .} \quad [22]$$

### Table 3 —Approximate Blank Diameters for Cylindrical Shells

(E. W. Bliss Co., Brooklyn, N. Y.)

| Diam. of Shell, in. | Height of Shell, inches | | | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1/2 | 5/8 | 3/4 | 7/8 | 1 | 1 1/8 | 1 1/4 | 1 1/2 | 1 3/4 | 2 | 2 1/4 | 2 1/2 | 2 3/4 | 3 | 3 1/4 | 3 1/2 | 3 3/4 | 4 |
| 1/4 | 0.75 | 0.83 | 0.90 | 0.97 | 1.03 | 1.09 | 1.15 | 1.25 | 1.34 | 1.43 | 1.52 | 1.59 | 1.67 | 1.75 | 1.82 | 1.89 | 1.95 | 2.02 |
| 3/8 | 0.94 | 1.04 | 1.13 | 1.21 | 1.28 | 1.34 | 1.42 | 1.55 | 1.67 | 1.78 | 1.88 | 1.98 | 2.07 | 2.16 | 2.24 | 2.32 | 2.40 | 2.48 |
| 1/2 | 1.12 | 1.22 | 1.32 | 1.41 | 1.50 | 1.58 | 1.66 | 1.80 | 1.93 | 2.07 | 2.18 | 2.29 | 2.39 | 2.50 | 2.60 | 2.69 | 2.78 | 2.88 |
| 5/8 | 1.28 | 1.40 | 1.50 | 1.60 | 1.70 | 1.79 | 1.88 | 2.04 | 2.19 | 2.32 | 2.46 | 2.58 | 2.69 | 2.80 | 2.92 | 3.02 | 3.12 | 3.23 |
| 3/4 | 1.44 | 1.56 | 1.67 | 1.78 | 1.89 | 1.98 | 2.08 | 2.25 | 2.41 | 2.56 | 2.70 | 2.84 | 2.96 | 3.09 | 3.21 | 3.32 | 3.43 | 3.54 |
| 7/8 | 1.59 | 1.72 | 1.84 | 1.95 | 2.06 | 2.16 | 2.26 | 2.45 | 2.62 | 2.78 | 2.94 | 3.08 | 3.22 | 3.38 | 3.50 | 3.63 | 3.75 | 3.84 |
| 1 | 1.73 | 1.87 | 2.00 | 2.12 | 2.23 | 2.34 | 2.45 | 2.64 | 2.82 | 3.00 | 3.16 | 3.31 | 3.46 | 3.61 | 3.74 | 3.87 | 4.00 | 4.13 |
| 1 1/8 | 1.87 | 2.02 | 2.15 | 2.28 | 2.40 | 2.51 | 2.62 | 2.83 | 3.02 | 3.21 | 3.37 | 3.53 | 3.69 | 3.84 | 3.98 | 4.12 | 4.26 | 4.39 |
| 1 1/4 | 2.01 | 2.16 | 2.30 | 2.43 | 2.56 | 2.68 | 2.80 | 3.01 | 3.22 | 3.40 | 3.58 | 3.75 | 3.91 | 4.07 | 4.22 | 4.37 | 4.51 | 4.65 |
| 1 3/8 | 2.16 | 2.31 | 2.45 | 2.59 | 2.72 | 2.84 | 2.96 | 3.18 | 3.39 | 3.59 | 3.77 | 3.95 | 4.12 | 4.28 | 4.44 | 4.59 | 4.74 | 4.88 |
| 1 1/2 | 2.29 | 2.45 | 2.60 | 2.74 | 2.87 | 3.00 | 3.12 | 3.36 | 3.58 | 3.77 | 3.97 | 4.15 | 4.33 | 4.50 | 4.66 | 4.82 | 4.97 | 5.12 |
| 1 5/8 | 2.42 | 2.59 | 2.74 | 2.89 | 3.02 | 3.15 | 3.28 | 3.52 | 3.74 | 3.95 | 4.15 | 4.34 | 4.53 | 4.70 | 4.87 | 5.03 | 5.20 | 5.35 |
| 1 3/4 | 2.56 | 2.72 | 2.88 | 3.03 | 3.17 | 3.30 | 3.43 | 3.68 | 3.91 | 4.14 | 4.34 | 4.54 | 4.73 | 4.90 | 5.08 | 5.25 | 5.42 | 5.57 |
| 1 7/8 | 2.70 | 2.86 | 3.02 | 3.18 | 3.32 | 3.46 | 3.59 | 3.84 | 4.08 | 4.30 | 4.52 | 4.71 | 4.91 | 5.10 | 5.28 | 5.45 | 5.62 | 5.79 |
| 2 | 2.83 | 3.00 | 3.16 | 3.31 | 3.46 | 3.61 | 3.75 | 4.00 | 4.24 | 4.47 | 4.69 | 4.90 | 5.10 | 5.29 | 5.48 | 5.65 | 5.83 | 6.00 |
| 2 1/8 | 2.96 | 3.13 | 3.30 | 3.46 | 3.61 | 3.75 | 3 89 | 4.16 | 4.40 | 4.64 | 4.86 | 5.08 | 5.28 | 5.48 | 5.67 | 5.85 | 6.03 | 6.21 |
| 2 1/4 | 3.09 | 3.27 | 3.44 | 3.60 | 3.75 | 3.90 | 4.04 | 4.31 | 4.56 | 4.80 | 5.03 | 5.25 | 5.46 | 5.66 | 5.86 | 6.05 | 6.23 | 6.41 |
| 2 3/8 | 3.22 | 3.40 | 3.57 | 3.74 | 3.89 | 4.04 | 4.18 | 4.46 | 4.72 | 4.96 | 5.20 | 5.42 | 5.64 | 5 84 | 6.04 | 6.24 | 6.42 | 6.61 |
| 2 1/2 | 3.35 | 3.54 | 3.71 | 3.87 | 4.03 | 4.18 | 4.33 | 4.61 | 4.87 | 5.12 | 5.36 | 5.59 | 5.81 | 6.02 | 6.22 | 6.42 | 6.61 | 6.80 |
| 2 5/8 | 3.48 | 3.67 | 3.84 | 4.01 | 4.17 | 4.32 | 4.47 | 4.76 | 5.03 | 5.28 | 5.52 | 5.76 | 5.98 | 6.20 | 6.40 | 6.61 | 6.80 | 6.99 |
| 2 3/4 | 3.61 | 3.80 | 3.98 | 4.15 | 4.31 | 4.47 | 4.62 | 4.90 | 5.18 | 5.44 | 5.68 | 5.92 | 6.15 | 6.37 | 6.58 | 6.79 | 6.99 | 7.18 |
| 2 7/8 | 3.75 | 3.93 | 4.11 | 4.28 | 4.45 | 4.60 | 4.76 | 5.05 | 5.33 | 5.59 | 5.84 | 6.08 | 6.32 | 6.54 | 6.76 | 6.96 | 7.17 | 7.37 |
| 3 | 3.87 | 4.06 | 4.24 | 4.42 | 4.58 | 4.74 | 4.90 | 5.20 | 5.48 | 5.74 | 6.00 | 6.25 | 6.48 | 6.71 | 6.93 | 7.14 | 7.35 | 7.55 |
| 3 1/8 | 4.00 | 4.19 | 4.38 | 4.55 | 4.72 | 4.88 | 5.04 | 5.34 | 5.63 | 5.90 | 6.16 | 6.40 | 6.64 | 6.87 | 7.10 | 7.32 | 7.52 | 7.73 |
| 3 1/4 | 4.13 | 4.32 | 4.51 | 4.68 | 4.85 | 5.02 | 5.18 | 5.48 | 5.77 | 6.05 | 6.31 | 6.56 | 6.80 | 7.04 | 7.26 | 7.48 | 7.70 | 7.91 |
| 3 3/8 | 4.26 | 4.45 | 4.64 | 4.82 | 4.99 | 5.15 | 5.31 | 5.62 | 5.92 | 6.19 | 6.47 | 6.72 | 6.96 | 7.20 | 7.43 | 7.66 | 7.87 | 8.08 |
| 3 1/2 | 4.39 | 4.58 | 4.77 | 4.95 | 5.12 | 5.29 | 5.45 | 5.77 | 6.06 | 6.35 | 6.61 | 6.87 | 7.12 | 7.37 | 7.60 | 7.83 | 8.05 | 8.26 |
| 3 5/8 | 4.51 | 4.71 | 4.90 | 5.08 | 5.26 | 5.43 | 5.59 | 5 90 | 6.21 | 6.49 | 6.76 | 7.03 | 7.28 | 7.52 | 7.76 | 7.99 | 8.21 | 8.43 |
| 3 3/4 | 4.64 | 4.84 | 5.03 | 5.21 | 5.39 | 5.56 | 5.73 | 6.04 | 6.35 | 6.63 | 6.91 | 7.18 | 7.43 | 7.68 | 7.92 | 8.16 | 8.38 | 8.60 |
| 3 7/8 | 4.77 | 4.97 | 5.16 | 5.34 | 5.52 | 5.69 | 5.86 | 6.18 | 6.49 | 6.78 | 7.06 | 7.33 | 7.59 | 7.84 | 8.08 | 8.32 | 8.55 | 8.77 |
| 4 | 4.90 | 5.10 | 5.29 | 5.48 | 5.66 | 5.83 | 6.00 | 6.32 | 6.63 | 6.92 | 7.21 | 7.48 | 7.74 | 8.00 | 8.24 | 8.48 | 8.71 | 8.94 |
| 4 1/8 | 5.02 | 5.22 | 5.42 | 5 61 | 5.79 | 5.96 | 6.13 | 6.46 | 6.77 | 7.07 | 7.36 | 7.63 | 7.89 | 8.15 | 8.40 | 8.64 | 8.88 | 9.11 |
| 4 1/4 | 5.15 | 5.35 | 5.55 | 5.74 | 5.92 | 6.09 | 6.27 | 6.60 | 6.91 | 7.21 | 7.50 | 7.78 | 8.05 | 8.31 | 8.56 | 8.80 | 9.04 | 9.27 |
| 4 3/8 | 5.28 | 5.48 | 5.68 | 5.87 | 6.05 | 6.23 | 6.40 | 6.73 | 7.05 | 7.35 | 7.64 | 7.93 | 8.20 | 8.46 | 8.71 | 8.96 | 9.20 | 9.44 |

**THERMAL COEFFICIENT OF EXPANSION** $f$, in Table 1, is used to estimate changes in lineal dimensions with changes in the temperature.

$$L_2 = L_1 + \{L_1 \times f \times (T_2 - T_1)\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [23]$$

where $L_1$, $L_2$ = respectively, initial and final lengths, in.; $T_1$, $T_2$ = respectively, initial and final temperatures, deg. F.

**YOUNG'S MODULUS OF ELASTICITY** $E_m$ (Table 1) permits computations of the elastic elongation $e$, in inches per inch of length, for any metal under a stress of $S$ lb. per sq. in., by means of the equation $e = S/E_m$.

**SPRING-BACK.**—Two ways of overcoming spring-back are: 1. *Overbend* to get the required angle. The amount of overbend usually is determined by trial and error. 2. *Hit-home* or bottom at the end of the bend to "set" the metal. In effect, this operation is a coining or squeezing operation, and the loads should be figured as such. The squeeze sets up compressive stress sufficient to overcome remaining internal tensile stresses.

## 4. MACHINE SELECTION

**FACTORS GOVERNING MACHINE SELECTION.**—Several factors are involved in machine selection. First, obviously, stroke, space for the dies, position and type of frame relative to handling and discharge of work, *i.e.*, vertical, inclined or horizontal, straight-sided or gap frame. Next, 1, capacity of frame, shaft, gearing (tons pressure); 2, fly-wheel (energy, to prevent stalling); and 3, motor.

**TONNAGE RATINGS** vary considerably with details of design and the conservativeness of the builder. Tables 4 and 5 give general values which take into consideration, the type of shaft, the stroke, the gearing and the frame, based upon well-developed designs.

**FLY-WHEEL ENERGY.**—The fly-wheel must store up and deliver at the proper instant, the energy required to maintain the working pressure throughout the working distance. In the case of long working strokes the motor may be able to take a material portion of this load. Otherwise it just restores energy to the fly-wheel during the balance of the cycle by bringing it back to speed.

**Fly-wheel Slowdown** is arbitrarily figured up to 10% for continuous running equipment; up to 20% for intermittent operating conditions; and occasionally up to 40% which approaches stalling. The working energy $W_e$, inch-tons, delivered by the average design of fly-wheel at 10% slowdown may be taken as

$$W_e = N^2 \times D_f^2 \times w_f/5{,}250{,}000{,}000. \quad \ldots\ldots\ldots \quad [24]$$

where = $N$ rev. per min.; $D_f$ = diameter of fly-wheel, in.; $w_f$ = weight of fly-wheel, lb. For 20% slowdown multiply $W_e$ by 1.9.

NOTE.—The above tonnage or pressure ratings are entirely independent of work or energy ratings. A long stroke press, if loaded to maximum pressure capacity through its maximum working stroke, will undoubtedly require additional fly-wheel and motor capacity.

NOTE.—The above tonnage or pressure ratings are entirely independent of work or energy ratings. A long stroke press, if loaded to maximum pressure capacity through its maximum working stroke, will undoubtedly require additional fly-wheel and motor capacity.

**MOTOR REQUIREMENTS.**—Motor sizes specified for punch presses usually are blanket recommendations to cover the wide range of work which may be put in the all-purpose press. They frequently are high for blanking, forging or coining operations, and low for deep drawing operations. In checking, the following approximations may be used:

$$\text{Hp.} = 0.005 \times W_e \times n, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [25]$$

where Hp. = horsepower of motor; $W_e$ = working energy, inch-tons; $n$ = number strokes per minute. Equation [25] holds good in cases where the fly-wheel has ample energy to meet the total requirements. Otherwise a check should be made with equation [26] and the higher value used in selecting the motor.

$$\text{Hp.} = 1.82 \times n \times (W_{e1} - W_{e2}) \div \theta \; . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [26]$$

in which $(W_{e1} - W_{e2})$ is the difference between the job requirements and the available fly-wheel energy. $\theta$ is the working portion of the cycle in degrees.

In equation [25] the motor may use the entire cycle to build up fly-wheel energy. In equation [26] it is selected to carry a portion of the working load. The motor lags some at the beginning of the demand, but then builds up to something over its rating to compensate. An allowance always must be made for friction losses and starting inertia losses, though these are small compared with average working loads.

Punch press motors must be capable of taking a slowdown up to about 10% on continuous running jobs, and up to about 20% (and higher on some jobs) for intermittently operating presses. Squirrel-cage motors are suitable for most work, but high-slip motors often are required on deep draws. Instantaneous peak loads may amount to 100% overload.

## 5. LUBRICANTS FOR WORKING METALS

**OIL.**—Many jobs may be done dry but better results and longer life of dies are obtainable by the use of lubricants. Oil lends itself to automatic lubrication by spray, drip, hollow punches, and wiper, and is often good for more than one operation. Usually an ordinary mineral oil is satisfactory.

As drawing conditions become more severe, a compounded oil of, say, 15% lard oil and 5% of wool fat in a mineral oil base is about as efficient as pure lard oil, and much less expensive. Occasionally, an unusually heavy job is considered to required heavy, crude oils which are very sticky and messy.

Electrical lamination steel often is lubricated with paraffin applied warm to the sheets. A mixture of paraffin oil and kerosene applied sparingly, to evaporate in the process, also is used.

**WATER-SOLUBLE LUBRICANTS.**—Oil lubricants are common, but ordinarily have to be cleaned off before annealing to prevent the oil burning into the steel. Again, they must be carefully cleaned off prior to soldering or to applying many finishes. For such reasons, water-soluble lubricants are widely used. These include soap solutions, flour, sulphunated oils, talc, amorphous chalk, zinc oxides, etc., in various mixtures which are more or less stable.

Fully automatic roll feed presses frequently are fitted with drip valves and felt rolls or wipers to spread the lubricant. Sometimes the drawing punches are drilled to carry oil or other lubricants to the work.

Co.; Treatise on Tool Room Grinding, Carborundum Co.; Table of Causes of Grinding Wheel Accidents, Independence Inspection Bureau; Safety Code for Use, Care and Protection of Abrasive Wheels, Am. Standards Assoc.; Operation of Grinding Wheels in Machine Grinding, Geo. I. Alden, *Trans.* A.S.M.E., xxxvi, p. 451, 1914.

## 1. ABRASIVE WHEELS

**SELECTION OF ABRASIVE WHEELS.**—The essential features governing the selection of a grinding wheel are: Grain, grade, bond, and structure, and the conditions of grinding that cause them to vary; methods of balancing and mounting; truing and dressing; effect on grain and grade of machine vibration and arc of contact; relation of work speed and wheel speed on production and finish; safeguards and dust removal systems.

Grinding wheels are made of abrasive grains of various sizes held together by a binder called the bond. Two types of manufactured abrasives and five types of bond are used. A few wheels are made of natural abrasive, as emery or corundum.

**ABRASIVES.**—The manufactured abrasives may be generally classified as aluminum oxide abrasives and silicon carbide abrasives. Both are products of the electric furnace, and are sold under various trade names, as Alundum, Aloxite, Borolon, Carborundum, Crystolon, etc.

A typical aluminum oxide abrasive is Alundum made by the Norton Co. by fusing bauxite in the electric furnace. Crystolon is a typical silicon carbide abrasive, made by the Norton Co., is produced by the electric furnace reaction of pure silica and coke. The aluminum oxide abrasives generally are used for grinding hard, tough and strong materials, are used for heavy duty work, such as snagging steel castings, and for cylindrical grinding on all but the hardest steels. Silicon carbide abrasives are hard and sharp, but not as tough as the aluminum oxide abrasives. They are used for snagging iron and brass castings, and for grinding materials of hard, dense grain structures. They also can be used to grind cemented carbide tools.

**GRAIN SIZE.**—Abrasive grains are designated by numbers corresponding to the number of meshes per lineal inch of the screen through which they are graded. Standard grain sizes are 8, 10, 12, 14, 16, 20, 24, 30, 36, 46, 60, 70, 80, 90, 100, 120, 150, 180, 220, and 240. The fine flours are classified hydraulically to the sizes 280, 320, 400, 500, and 600.

**BOND.**—Five types of bond are used in grinding wheels, as follows: 1. Vitrified bond, consisting of a clay mixture, subjected to a sufficiently high temperature to fuse to a molten glass condition. Vitrified wheels are strong, and can be used for very heavy work, and for the rapid removal of material. 2. Silicate bond, consisting of a mixture of silicate of soda and minerals, which at comparatively low temperatures form a hard cement. Silicate bond releases the grain more readily than does vitrified bond. Wheels with silicate bond are used on work where the heat generated by grinding must be kept at a minimum, as edge tools. 3. Shellac bond, comprising organic materials which melt at low temperatures, but attain a permanent set at slightly higher temperatures. Shellac bond wheels will impart high finishes to such work as cam-shafts and steel mill rolls. They are used for light cuts and for gumming and sharpening saws, and for cut-off wheels. 4. Rubber bond consists of rubber mixed with certain minerals in definite proportions, which on vulcanization, produces the desired hardness and toughness. Rubber bond wheels are used for high-speed grinding, and for rapid stock removal. Cut-off wheels with rubber bond can be made thin enough to reduce to a minimum the stock lost in making a cut. 5. Synthetic resin bond, as resinoid. Wheels with this type of bond are used for high-speed work in foundries and billet shops. They will operate at 9500 surface feet per minute in swing frame grinders for snagging castings and removing scale from billets. Cut-off wheels with resinoid bond will operate at 16,000 surface feet per minute.

**GRADE** is a term denoting the hardness or strength of a grinding wheel. It does not express the hardness of the abrasive itself. Hardness of abrasive grain and the grade of the wheel are quite different. A grinding wheel may be made of a very hard abrasive and still be a soft wheel. A wheel is hard when the retentive powers of the bond are great. If grains of abrasive easily are broken out of the bond, the wheel is soft. A wheel is of the proper grade when the cutting grains automatically are replaced when dulled. Wheels that are too hard will glaze and must be resharpened by dressing. The points of the dresser break out and break off the cutting grains by percussion.

While the ideal way to measure grade is to grind on each wheel, the best known practicable method is to measure the resistance offered by the wheel to the penetration of a steel cutting tool. Under a uniform pressure the tool will penetrate deeper into a softer wheel than a hard one. The resistance against turning the tool is less in a softer wheel than in a hard one. Grades are designated so that there is a gradual change in the grading from the extremely hard wheel to the extremely soft one. The practice of the various grinding wheel manufacturers in grading differs.

Most manufacturers use a letter following the grain symbol to designate the grade of the wheel. Unfortunately these letters and their relation to each other do not always mean the same thing. In the Carborundum Co. scale of grades the letters at the beginning of the alphabet indicate the hardest grades and those at the end of the alphabet the softest. Norton Co. and most of the other manufacturers use the alphabet scale in the reverse order, while a few manufacturers use special code arrangements of the letters.

For rubber, synthetic resin and shellac bonded wheels, the grade is sometimes designated by letters, sometimes by numbers. Norton Co. formerly used numbers but now uses letters to unify the system with that used for vitrified and silicate wheels. Carborundum Co. uses numbers from 1 to 8, No. 1 being the hardest and No. 8 the softest, while many others use the number system in the reverse order.

**STRUCTURE** designates the spacing of the abrasive grains in the wheel. The same total volume of voids in two different wheels may be made up of a relatively small number of voids of large volume, or of a large number of small volume. The cutting action of the two wheels will be different, although they may be of the same grain and grade. In general, wheels with the wider grain spacing will have longer life than those with close grain spacing.

Structure is denoted by numbers. The system of numbers used by the Norton Co. assigns the numbers 0, 1, 2, 3 to close spacings; the numbers 4, 5, 6 to medium spacings, and the numbers 7, 8, 9, 10, 11 and 12 to the wide spacings.

**Table 1.—Grinding Wheel Symbol Components**

| Abrasive | | Grain | Grade | | Structure | | Bond | |
|---|---|---|---|---|---|---|---|---|
| Kind | Designation | | Character | Designation | Spacing | Designation | Kind | Designation |
| Alundum | Blank | See paragraph "Grain size" p. 21–66 | Very soft | E, F, G | Close | 0, 1, 2, 3 | Vitrified | Blank |
| 38 Alundum | 38 | | Soft | H, I, J, K | Medium | 4, 5, 6 | "B" Vitrified | B |
| 19 Alundum | 19 | | Medium | L, M, N, O | Wide | 7, 8, 9, 10, 11, 12 | Silicate | S |
| 15 Alundum | 15 | | Hard | P, Q, R, S | | | Resinoid | T |
| 35 Alundum | 35 | | Very hard | T, U, W, Z | | | Rubber | R |
| Crystolon | 37 | | | | | | Shellac | L |
| | | | | | | | "V" Shellac | V |

**WHEEL MARKING.**—Grinding wheels are marked with a symbol that completely describes and identifies the wheel. The practice of the several manufacturers varies. The system used by the Norton Co. is given below.

The symbol consists of numerals and letters, which, by their position, indicate a particular characteristic of the wheel as follows:

| Position No. ........ | 1 | 2 | 3 | 4 | 5 |
|---|---|---|---|---|---|
| Represents......... | Abrasive | Grain | Grade | Structure | Bond |
| Example........... | 38 | 46 | K | 5 | B |

The complete symbol is 3846–K5B, which represents a wheel of 38 brand Alundum abrasive, 46 grain size, grade K, structure 5, vitrified bond B. The significance of the various numbers and letters used in the symbols is given in Table 1.

**DIAMOND WHEELS.**—Wheels in which the abrasive surface is formed of diamond dust are used extensively for the grinding and lapping of cemented carbide tools and inserts, and for cutting up cemented carbide shapes. These wheels are made in a variety of sizes and shapes for use on the several types of tool and cutter grinders. In the smaller sizes, up to, say, 1 $^3/_{16}$ in. diameter by $^1/_4$ in. face, they are made solid; in the larger sizes, up to, say, 12 in. diameter, they are made with a relatively thin section of diamond on the periphery or other working surface. The sizes of abrasive used are Nos. 100, 220, and 320. For grinding, No. 100 abrasive should be used. No. 220 grain is used in wheels for lapping operations to produce keen cutting edges, and the No. 320 grain wheel is used to lap highly finished surfaces and to produce microscopically keen cutting edges.

The usual tool grinding speeds are satisfactory for diamond wheels. Water is a satisfactory coolant, if the flow can be maintained constant. In the absence of a cooling system, the surface should be lubricated freely with light machine oil. Cooling with oil or water will prolong the life of the wheel.

## 2. FACTORS AFFECTING GRINDING WHEEL SELECTION

Selection of a grinding wheel for a given operation involves consideration of the more or less fixed conditions into which the wheel must fit, and also of the factors that may be modified to suit the fixed conditions.

**FIXED CONDITIONS. 1. Material to be Ground.**—The physical properties of the material to be ground govern the type of abrasive to be used. Materials of high tensile strength, from hard, tough alloy steels to the tougher varieties of bronze, some of the aluminum alloys, and materials that are neither brittle nor easily penetrated, require aluminum oxide wheels. Different degrees of hardness, toughness and ductility in metals are handled by aluminum oxides of varying degrees of temper. See Tables 6 and 7.

Materials of low tensile strength, and which are penetrated easily, as soft brasses and bronzes, cast and chilled iron, aluminum, copper, marble, stone, glass, wood, leather, etc., should be ground with silicon carbide wheels.

In general, hard, dense materials require a relatively soft wheel. A large number of cutting points is necessary in the wheel, since the penetration of each point is slight. These points may be obtained by the use of a fine-grain wheel or a dense structure, if the use of fine grain is inadvisable. Exceptionally hard materials, as tungsten carbides, are best ground with open grain wheels. Soft, tough and ductile materials require an open grain wheel.

**2. Amount of Material to be Removed.**—For relatively large stock reduction, coarse grain wheels with open structure should be used, particularly for off-hand snagging of castings. Where finish is of importance, a closer structure should be used. Finish depends largely on grain size, except in machine grinding. Here, proper truing facilities enable a fine finish to be obtained with coarse grain wheels.

**3. Area of Contact.**—Proper grain size, grade and structure depend on the area of contact between wheel and work, because of the relation between area of contact and unit working pressure. Cylindrical grinding is an example of high unit pressure and small area of contact. Such conditions call for a wheel of fine grain, closely spaced structure to distribute the pressure over a large number of cutting points, none of which is subjected to excessive pressure. The grade should be medium hard, to prevent excessively fast wheel wear, since the forces tending to tear the grains from the wheel are great.

Surface grinding, with the rim of a cup-shaped wheel in contact with the surface of the work, is an example of high total pressure of wheel on the work, but of low unit pressure. The wheel characteristics under such conditions would be coarse grain, with widely spaced structure, to distribute the pressure per unit of area over a small number of cutting points, each receiving sufficient pressure to cut efficiently. The grade should be soft, in order that the dull grains may be released promptly, as the forces tending to tear them from the wheel are light.

**4. Type of Grinding Machine.**—The grinding machine usually is already installed, and imposes conditions that must be considered in wheel selection. Heavy, rigid machines require wheels that are softer and of more open structure than wheels for light, flexible machines. Machines that vibrate require finer grain wheels, of harder and denser structure, than the wheels for more rigid machines. Feed and speed combinations on precision grinding machines will affect the wheel characteristics. Surface grinding machines using cup wheels require softer wheels of more open structure than do similar machines using straight or disc wheels.

**VARIABLE FACTORS.—A. Wheel Speed.**—Too slow a speed wastes abrasive without corresponding useful work. Excessive speed may result in hard grinding action and danger of breakage. It is best to operate a grinding wheel close to the speed recommended by the maker. The grits, grades and structures recommended for given grinding operations are based on the recommended speeds. If these speeds cannot be used, the grade at least should be changed to meet this changed condition. Table 2 gives the peripheral speeds recommended for various classes of work.

**B. Work Speed.**—In machine grinding, high work speed tends to wear the wheel faster than slow work speed. Wheel wear depends on the ratio of wheel speed to work speed, both in surface feet per minute. The higher the ratio, the less work the wheel is required to do in a given time, and the wheel wears at a lower rate. A decreased ratio, resulting from increased work speed, requires the wheel to do more work in a given time and to wear faster. In general, the longer the arc or the larger the area of contact in precision

**Table 2.—Recommended Wheel Speeds for Various Classes of Grinding**

| Type of Grinding | Wheel Speed, Surface Feet per min. |
|---|---|
| Cylindrical grinding | 5,500– 6,500 |
| Cutter and tool grinding | 4,500– 6,000 |
| Internal grinding | 2,000– 6,000 |
| Snagging, off-hand grinding (vitrified wheels) | 5,000– 6,000 |
| Snagging (rubber and Resinoid wheels) | 7,000– 9,500 |
| Surface grinding | 4,000– 6,000 |
| Knife grinding | 3,500– 4,500 |
| Hemming cylinders | 2,100– 5,000* |
| Wet tool grinding | 5,000– 6,000 |
| Cutlery wheels | 4,000– 5,000 |
| Rubber, shellac and Resinoid cutting-off wheel | 9,000–16,000* |

* Higher speed recommended only if bearings, protection devices and machine rigidity are adequate.

**Table 3.—Revolutions per Minute for Various Surface Speeds**

| Diameter, in. | Surface Speeds, Feet per Minute | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1,000 | 2,000 | 3,000 | 4,000 | 5,000 | 6,000 | 7,000 | 8,000 | 9,000 | 10,000 | 12,000 | 14,000 | 16,000 |
| | Revolutions per Minute | | | | | | | | | | | | |
| 1 | 3,820 | 7,639 | 11,459 | 15,279 | 19,099 | 22,918 | 26,738 | 30,558 | 34,377 | 38,196 | 45,836 | 53,474 | 61,116 |
| 2 | 1,910 | 3,820 | 5,730 | 7,639 | 9,549 | 11,459 | 13,369 | 15,279 | 17,188 | 19,098 | 22,918 | 26,737 | 30,558 |
| 3 | 1,273 | 2,546 | 3,820 | 5,093 | 6,366 | 7,639 | 8,913 | 10,186 | 11,459 | 12,732 | 15,278 | 17,826 | 20,372 |
| 4 | 955 | 1,910 | 2,865 | 3,820 | 4,775 | 5,729 | 6,684 | 7,639 | 8,595 | 9,549 | 11,459 | 13,368 | 15,278 |
| 5 | 764 | 1,528 | 2,292 | 3,056 | 3,820 | 4,584 | 5,347 | 6,111 | 6,876 | 7,640 | 9,168 | 10,696 | 12,224 |
| 6 | 637 | 1,273 | 1,910 | 2,546 | 3,183 | 3,820 | 4,456 | 5,093 | 5,729 | 6,366 | 7,639 | 8,913 | 10,186 |
| 7 | 546 | 1,091 | 1,637 | 2,183 | 2,728 | 3,274 | 3,820 | 4,365 | 4,911 | 5,456 | 6,548 | 7,640 | 8,732 |
| 8 | 477 | 955 | 1,432 | 1,910 | 2,387 | 2,865 | 3,342 | 3,820 | 4,297 | 4,775 | 5,729 | 6,685 | 7,640 |
| 10 | 382 | 764 | 1,146 | 1,528 | 1,910 | 2,292 | 2,674 | 3,056 | 3,438 | 3,820 | 4,584 | 5,348 | 6,112 |
| 12 | 318 | 637 | 955 | 1,273 | 1,591 | 1,910 | 2,228 | 2,546 | 2,864 | 3,183 | 3,820 | 4,456 | 5,092 |
| 14 | 273 | 546 | 818 | 1,091 | 1,364 | 1,637 | 1,910 | 2,183 | 2,455 | 2,728 | 3,274 | 3,820 | 4,366 |
| 16 | 239 | 477 | 716 | 955 | 1,194 | 1,432 | 1,671 | 1,910 | 2,149 | 2,387 | 2,865 | 3,342 | 3,820 |

grinding operations, the faster should be the work speed, in order to have the wheel cut properly. In off-hand grinding, the rate at which the work is forced against the wheel or the method of applying the work influences grade selection. The harder the grinding wheel is forced, the harder should be the wheel for abrasive economy. This relation also exists in semi-automatic and high-production precision grinding.

**C. Condition of Grinding Machine.**—The grinding wheel cannot work to good advantage on a machine in poor repair or improperly set up. If conditions are bad, allowances must be made in the selection of the wheel grade. Spindles loose in the bearings require much harder wheels than do normal conditions. Insecure or shaky foundations necessitate hard grades to overcome the tendency of the wheel to wear rapidly, cutting qualities being sacrificed thereby.

**D. Skill of Workmen.**—Grinding costs on off-hand grinding may vary 100% on some work with the same kind of machine in the same factory due to the difference in the method of applying the work to the wheel, and to the variation of skill and knowledge of the different workmen. Even in machine grinding, the operator can vary the results in grinding castings by his methods of handling the machine. The foregoing considerations are summarized in Table 5. Table 6 gives the type, grain and grade of wheel recommended for various classes of grinding.

**Table 5.—Factors Influencing the Selection of Abrasive Wheels.** (Norton Co.)

| Selection of | Influential Factors | Kind of Wheel | Material Ground, Result Desired, or Condition To Be Met |
|---|---|---|---|
| Abrasive | Physical Properties of Material Ground | Alundum | Carbon, alloy or high-speed steel; annealed malleable iron; wrought iron; tough bronzes; tungsten, etc. |
| | | Crystolon | Gray iron; chilled iron; brass; soft bronze; aluminum; copper; marble; granite; pearl; rubber; leather; very hard alloys as tungsten-carbide, etc. |
| Grain | Amount of Material to be Removed | Coarse grain | Fast removal of stock |
| | Finish Desired | Fine grain | Fine finish |
| | Physical Properties of Material to be Ground | Coarse grain | Soft, ductile materials |
| | | Fine grain | Dense, hard or brittle material |
| Grade | Physical Properties of Material to be Ground | Hard Wheel | Soft material |
| | | Soft Wheel | Hard material |
| | Area of Contact | . . . . . . . . . . . . . . | Hardness increases as area of contact decreases |
| | Wheel Speed | Hard Wheel | Low wheel speed |
| | | Soft Wheel | High wheel speed |
| | Work Speed | Hard Wheel | High work speed |
| | | Soft Wheel | Low work speed |
| | Condition of Grinding Machine | Hard Wheel | Machine in poor condition |
| | | Soft Wheel | Machine in good condition |
| | Skill of Operator | Harder Wheels | Unskilled operator; piece work |
| | | Softer Wheels | Skilled operator; day work; economical production |
| Structure | Physical Properties of Material to be Ground | Wide Spacing | Soft, tough, ductile materials |
| | | Close Spacing | Hard, brittle materials (except cemented carbides) |
| | Finish Desired | Wide Spacing | Medium or coarse finish |
| | | Close Spacing | Fine finish |
| | Nature of Operation | Wide Spacing | Snagging; operations with flexible application of pressure; surfacing |
| | | Medium Spacing | Cylindrical, centerless, tool and cutter grinding |
| | | Close Spacing | Heavy pressures tending to deform wheel |
| Bond | Wheel Dimensions | Vitrified | For general use; rapid removal of stock |
| | | Silicate | Solid wheels over 36 in. diameter |
| | | Synthetic Resin<br>Shellac<br>Rubber | Thin cutting-off wheels; wheels subject to deflection |
| | Operating Speed | Vitrified | Wheel speeds up to 6500 surface ft. per min. |
| | | Synthetic Resin<br>Shellac<br>Rubber | Wheel speeds above 6500 surface ft. per min. |
| | Finish Desired | Synthetic Resin<br>Shellac<br>Rubber | High finish where high production is not a factor |
| | | Silicate | To replace sandstone on cutlery, etc. |

## Table 6.—Grinding Wheel Recommendations

Based on the Norton Co. system of wheel marking. See p. 21–67.

**GRINDING WITH PORTABLE EQUIPMENT.**—Portable grinders have come into wide use in foundries and steel mills for snagging, cleaning and smoothing of castings and billets, and in industries such as steel furniture and automobile body, and in tool rooms and die shops where they are used as production tools. The wheels used generally are smaller than those used in stationary or swing frame grinders, and are driven at higher speeds by electric motor or air turbine. The grain, grade and other properties also are different in portable equipment. Table 7 gives typical examples of wheel recommendations made by the Norton Co. for portable equipment.

The following recommendations * are made for wheels for use in portable equipment in the tool room and die shop:

**Internal Grinding.**—For hardened or high-speed steels, 3846–J, aluminum oxide, vitrified; soft steels, 3846–K aluminum oxide, vitrified; cast iron, 3736–H silicon carbide, vitrified.

**Surfacing.**—Tool and die steels, 3846–K5B, aluminum oxide, vitrified.

**General Purpose Grinding.**—Tool and die steels, 3846–L5B aluminum oxide, vitrified.

**Off-hand Grinding.**—Dies, metal patterns and molds, from 36 to 60 grain size, grade P to R, aluminum oxide, vitrified, or 30–Q4T–2 aluminum oxide, resinoid; steel castings and forgings, 36–P5B aluminum oxide, vitrified; grinding keyways, slotting or cutting off small stock with wheels $^1/_{16}$ to $^1/_8$ in. thick, 60–P8T–2 aluminum oxide, resinoid.

---

* For significance of the wheel symbols, see p. 21–67.

**WHEELS FOR SURFACE GRINDING.**—Vertical-spindle surface grinders and face grinders use wheels of the cup form, the grinding surface being the edge of the rim of the wheel. Built-up sectional wheels frequently are used in place of solid cup wheels both for surface grinders and for disc grinders.

The Bridgeport Safety Emery Wheel Company, Bridgeport, Conn., makes a wheel consisting of segments mounted in a steel chuck. The segments can be moved outwards from the face of the chuck to compensate for wear. Number of segments ranges from 8, in a 16-in. wheel, to 18 in a 42-in. wheel. The depth of the segments is 8 in. in all cases, and practically this whole depth can be worn away in the use of the wheel.

Another form of disc or cup wheel is the Besly wheel, which consists of a ring or segments of abrasive, cemented to a thin ribbed steel back, through which studs project for attaching it to the adaptor or face plate of the grinding machine. This type of wheel also permits 100% of the abrasive material to be used.

The Norton Co. recommends for surfacing the various grades and types of disc wheels shown in Table 8.

**ALLOWANCE FOR GRINDING.**—The amount of material allowed for removal by grinding varies with the character of the work and the type of machine. In cylindrical grinding it may range from 0.020 to 0.025 in. In internal grinding, allowances have ranged, depending on the class of work, from 0.006 to 0.008 in. and from 0.012 to 0.017 in.

**GRINDING TOLERANCES** have decreased with improvement in grinding machines and in grinding wheels. On cylindrical grinding tolerances in diameter of − 0.0000 to + 0.0005 in. are possible of attainment, and in out of roundness and in taper, tolerances of 0.000 05 have been specified. Tolerances smaller than these fall within the fields of lapping and honing.

**INTERNAL GRINDING OF SMALL AND MEDIUM SIZE HOLES.**—C. R. Alden describes (*Trans.* A.S.M.E., MSP 51–15, 1929) the grinding of holes as small as $^1/_{16}$ in. diam. An air turbine was used to give a spindle speed of 65,000 r.p.m. The wheel was a mounted point, that is, an abrasive tip cemented on a steel shank, substantially less in diameter than the tip, which in turn was smaller than the hole to be ground. An important consideration in the internal grinding of small holes is the type of grinding spindle and the bearings used. A solid projection type of spindle, in which the wheel is mounted on an integral projection of the spindle, was found to be best. The projection should be of the largest possible diameter and shortest possible length consistent with the diameter of the hole to be ground. This will limit the amount of wheel wear that can be permitted, since allowance of excessive wheel wear will necessitate a spindle and bearings

that will lack rigidity. It is recommended that 2-in. wheels for grinding 2-in. holes be allowed $^1/_2$ in. reduction of diameter by wheel wear, and that they then be transferred to the grinding of 1 $^1/_2$-in. holes, with a further allowance of $^3/_8$ in. for wheel wear, after which they could be used for the grinding of 1 $^1/_8$ in. or 1-in. holes. The wheel thus can be used up, and at the same time the conditions under which it works will be those of maximum efficiency. Fig. 1 shows the spindle speeds recommended for the grinding of small holes.

**GRAIN DEPTH OF CUT.**—An analysis of the action of the wheel when in operation shows how theoretical considerations bear out the truth of the empirical rules for the use of grinding wheels in machine grinding. A paper by Geo. I. Alden (*Trans.* A.S.M.E., xxxvi, p. 451, 1914) gives the essential distinction between the radial or real depth at which the wheel cuts and the depth which the abrasive grain in the wheel cuts into the material being ground. The latter depth is termed the "grain depth of cut." This grain depth of cut is the controlling factor in securing the correct working of the wheel. A formula is deduced for computing the grain depth of cut, the application of the analysis is explained and these conclusions reached by Prof. Alden: 1. Other factors remaining constant, increase of work speed increases grain depth of cut, and makes a wheel appear softer. 2. A decrease of wheel speed increases grain depth of cut. 3. Diminishing the diameter of the wheel increases the grain depth of cut; increasing the diameter of the wheel decreases the grain depth of cut. 4. Decreasing the diameter of work increases the grain depth of cut; conversely, increasing the diameter of work decreases the grain depth of cut. A table of arcs of contact of wheel and work for a limited range of diameters is given, also a table of values of one of the factors in the formula for grain depth of cut.

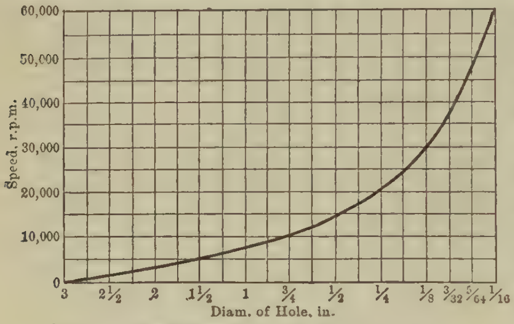

Fig. 1. Wheel Speeds for Grinding Small Holes

W. H. Chapman (*Trans.* A.S.M.E., xlii, p. 595, 1920), basing his study on Prof. Alden's paper set forth above, gives a mathematical analysis of the laws involved in cylindrical grinding and an analysis for grinding action for both draw-in and traverse cuts, deriving formulas and from them drawing practical conclusions as to the best methods to follow for maximum grinding efficiency.

**Draw-in Cuts.**—For draw-in cuts, the maximum depth of chip, in inches, corresponding to Prof. Alden's grain depth of cut, is given by

$$G = (\mu u/V)\,(\sqrt{2f/r}),\ \text{approximately} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [1]$$

where $G$ = maximum depth of chip, in., $\mu$ = intervals between grains of wheel in fractions of an inch, $u$ = work speed, ft. per min., $V$ = surface speed of wheel, ft. per min., $f$ = depth of cut, in., on work radius, $r$ = radius of work, in.

The index of the wheel-wearing action, $W_1$, due to grinding, is

$$W_1 = (\mu u/V^2)\,(\sqrt{2f/r}) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [2]$$

The actual wheel-wear can be computed by multiplying the value of $W_1$ by a constant derived by experiment, which may be taken as $(1800 \times 10^4)$. The amount of metal removed per minute may be determined by

$$P = 2\pi r f w \times \text{r.p.m.}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [3]$$

where $P$ = cu. in. of metal removed per min., $w$ = width of wheel, in., and r.p.m. = speed of rotation of the work, other notation as before.

Table 9 compares wheel-wear and quantity of metal removed at different work speeds in a given machine, as calculated from the above formulas. Note that wheel-wear values increase rapidly as work speed increases. The value of 0.0166 for work 1 in. diameter at 53 r.p.m. becomes 0.1040 for work 4 in. diameter at 167 r.p.m. A wheel sufficiently soft to cut freely in the first case would wear so fast as to be nearly useless in the second case. Where the wheel-wear values are nearly the same, however, the same wheel will act properly in both cases, as, for instance, on 1-in. work at 138 r.p.m. and 4-in. work at 72.5 r.p.m. From Table 9, and by experimental tests with various wheels, certain ranges of wheel-wear values may be found to correspond to different grades of suitable grain size and abrasive for the material to be ground, and wheel-wear indices may be computed for any set of conditions to enable the proper wheel to be selected.

Production can be increased with a minimum increase in wheel-wear by an increase in the feed, up to the limit of the grain penetration. An example in the paper shows that doubling the feed approximately doubled the production but increased the wheel-wear only 35%. Doubling the work speed, on the contrary, doubled both production and wheel-wear.

**Traverse Cuts.**—The index of wheel-wear for traverse cuts is

$$W_t = (\mu u/V^2)\{u/(\sqrt{T^2 + u^2})\}\,(\sqrt{2f/r}), \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [4]$$

where $T$ = traverse speed, ft. per min., other notation being as before. The expression $\{u/(\sqrt{T^2 + u^2})\}$ is known as the traverse factor. Where $T$ is large with respect to $u$ the factor will be appreciably less than unity, but as $u$ increases the reduction in wheel-wearing action is less pronounced. A table of wheel-wear values for traverse cuts can be made by multiplying the traverse factors determined as above by the wheel-wear value for the corresponding work speed and work diameter for draw-in cuts, such as are given in Table 9. Table 10 is such a table compiled for the same machine as was Table 9. By assigning certain wheels to specified ranges of wheel-wearing action, the proper wheel for traverse cuts may be selected from Table 10. The wheel used, however, would be some-

what softer in the traverse cut for the same index figure, because the actual depth of cut does not follow the indicated depth, as shown by the feeding mechanism, as closely for traverse work as for draw-in work. The following wheels are found to be satisfactory for traverse cuts on mild steel under the assumed conditions:

| Wheel Designation.... | 36 or 46I | 36 or 46J | 36 or 46K | 36 or 46L | 36 or 46M |
|---|---|---|---|---|---|
| Wheel-Wear Values, in Table 9............ | 0.0250 | .0250–.0400 | .0400–.0500 | .0500–.0600 | .0600 |

**Practical Conclusions.**—The practical conclusions drawn from the foregoing mathematical analysis are: The power drive must maintain the speed constant except as changed by the operator. The wheel must be in good running balance and in absolute truth, and held in position relative to the work within the closest possible limits. The work must be accurately held with respect to the wheel and must be uniformly rotated. The relative traverse between work and wheel must be uniform. The work must be rigidly supported over its entire length and no vibration allowed to occur between centers. Feeding must be at a rate such that the feed increment never exceeds the maximum grain penetration. Work must be kept at a uniform temperature and local heating prevented. A copious supply of grinding compound should be directed to the arc of contact at all times. In truing a wheel with a diamond, the cooling medium is vital to accuracy. Never feed a diamond over 0.001 in. per traverse. Do not try to use a single wheel for a variety of work sizes or materials.

## 3. CARE AND USE OF GRINDING WHEELS

**CARE OF GRINDING WHEELS.**—Wheels should be examined upon receipt to make sure that they have not been damaged in transit or otherwise. Each wheel should be held free and clear and tapped lightly with the handle of a screw driver. A wheel in good condition will give a clear ringing sound, while the absence of such ringing indicates a cracked wheel. Damp wheels or those in which the spaces between the grains are filled with sawdust, and also rubber and shellac-bonded wheels, will not ring when tapped.

Wheels should be stored in dry places of even temperature. Shellac- and rubber-bonded wheels, $^1/_4$ in. or less thick, should be laid flat on a straight surface to prevent warping. All other wheels should be supported on edge in racks. Before mounting, all wheels should be inspected again, as a wheel sometimes may crack merely by falling over from an upright position. The same " ring " test should be applied before mounting.

**OPERATING CONDITIONS. Work Rest.**—The work rest should be adjusted close to the work at all times, the maximum space between wheel and rest being $^1/_8$ in. The work rest should be of rigid construction and should be securely clamped after each adjustment. Adjustments should not be made while the wheel is in motion. Many wheel breakages are caused by work being caught between wheel and rest.

**Truth and Balance.**—The keeping of wheels true should be the function of especially experienced men. An inexperienced man frequently puts a wheel in worse condition than before. Wheels should be tested occasionally for balance. If out of balance, and the condition cannot be corrected by truing or dressing, the wheel should be removed from the machine. Wheels used for wet grinding should not be allowed to stand partly immersed in water, as the water absorbed may throw the wheel dangerously out of balance.

**Application of Work.**—When starting a wheel, the operator should stand aside until the wheel has run at full speed for at least one minute. Where work is applied continuously to the wheel, the heat generated should not be allowed to increase to a point where it will break the wheel. The generation of large amounts of heat may be overcome by a change in the grade of the wheel or by the application of a steady stream of water to the point of contact.

Grinding on the side of a straight wheel is prohibited in some places. Some classes of work, however, require the use of the side of the wheel for grinding. It is difficult to set a fixed rule as to when this practice is permissible, as each case must be considered individually. It should be remembered that thin wheels are not as strong as thicker ones and also that coarse wheels and those of softer grades can be broken more easily than the finer and harder wheels. If it is necessary continually to use the straight side of a wheel or to exert considerable pressure, cup wheels should be used.

**Eye Protection.**—Where danger of eye injury exists, operators should be provided with goggles. These should be so constructed that the lenses will be held firmly in the frame in case of breakage. To protect against fine flying dust, the frame should fit snugly around the eyes, following the contour of the face. The type of goggle held in place by an elastic head band has been found more satisfactory than those held in place with metal temple bows.

Shields of plate glass held in a metal frame fastened to the machine just above the point on the wheel where the work is done have proved quite satisfactory for certain classes of work.

**Wheel Mounting.**—Wheel flanges should be made in accordance with the dimensions in Tables 11, 12, 16 and 17. The inner flange should be keyed, shrunk or screwed to the spindle. The outer flange always should be of exactly the same diameter as the inner flange. The hole in the outer flange should be an easy sliding fit on the spindle or arbor. All flanges should be relieved or recessed at the center for at least 1/16 in. in order that the flanges may bear at the outer edge only. Flanges of the adapter and sleeve types, Table 12, should be recessed so that there is no bearing on the wheel within 1/8 in. of the hole. All flanges must be true and in balance.

| | 18 | 19 1/2 | 3/4 | 1/2 |
| | 20 | 21 1/2 | 3/4 | 1/2 |

Compressible washers of blotting paper, rubber or leather should be used between the wheel and the flanges to compensate any slight unevenness in the surface of the wheel and to insure a uniform bearing around the entire periphery of the flange. Before mounting, both wheel and flange should be cleaned of foreign particles. The nuts should be tightened only enough to hold the wheel firmly. Excessive tightening may damage the wheel.

Other forms of mounting, such as cementing or sulphuring the wheel to iron backs and centers, or the clamping of segments to a metal ring are recommended only for special purposes and no definite specifications can be given. Mounting wheels with tapered holes and tapered arbors demands great care. Any forcing of the wheel necessary to get it in position tends to crack it.

**OPERATING SPEED.**—All types of wheels do not possess equal strength, and consequently it is not safe to operate them all at equal speeds. As a general rule, vitrified and silicate bonded wheels are classified in one group and the organic bonded wheels (shellac, rubber, and Bakelite) in another. Vitrified and silicate wheels are relatively brittle and a maximum operating speed of 6500 surface feet per minute has been established for this group. Wheels in the softer grades and of coarse grain size should not be operated as fast as this. The organic bonded wheels are more elastic and can be operated at higher speeds with safety. A maximum operating speed of 9500 surface feet per minute has been established for this group, with the exception of thin cutting-off wheels which may be operated up to 16,000 surface feet per minute under certain conditions. In the organic group as in the vitrified and silicate group, the operating speeds for the softer and coarser wheels should be lower.

The manufacturers of grinding wheels know from experience the maximum speeds at which the various wheels they produce should be operated. It is the usual custom to show this maximum operating speed on tabs accompanying the wheels. It is also customary to test all wheels 6 in. and larger in diameter at speeds sufficiently higher to insure a reasonable factor of safety.

Table 13 shows the maximum peripheral speed per minute permitted by the A.S.A. Safety Code for various types of wheels and bonds.

**FACTOR OF SAFETY.**—Since the centrifugal force tending to break a wheel increases as the square of the speed, it is, at 9000 surface ft. per min. 2.3 times greater than at 6000 surface ft. per min., and 3.3 times greater than at 5000 surface ft. per min. These values, 2.3 and 3.3, are called the established factor of safety for the operating speeds mentioned.

$$\text{Established factor of safety} = \text{testing speed}^2 \div \text{operating speed.}^2$$

$$\text{True factor of safety} = \text{breaking speed}^2 \div \text{operating speed.}^2$$

The true factor of safety cannot be calculated unless the breaking speed actually is measured. Experience shows the true factor of safety to be, usually, many times greater than the established factor.

The forces tending to break grinding wheels are due to other causes in addition to speed of rotation. Among these are: Poor mountings, wheel flanges of unequal diameter, unrelieved flanges, expansion from excessive and rapid heating of one periphery, work catching between wheel and work rest, improper grinding on side of wheel and excessive out-of-truth, or out-of-balance conditions. These conditions are cumulative and increase the breaking stresses due to rotation. Since these conditions exist, the established factor of safety is kept large. If the grinding conditions are correct, the wheel which has been subjected to the speed test should not give trouble, as it has been established that it is

**Table 13.—Maximum Permissible Grinding Wheel Speeds**

| Type of Wheel | Vitrified and Silicate Bonds | | | Organic Bonds | | |

sufficiently strong to withstand the stress due to ordinary grinding conditions. A thorough investigation of a grinding wheel broken in operation usually will show the breakage to have been due to faulty operating conditions and not to the wheel itself.

**SIZE OF WHEEL SPINDLE.**—The minimum diameter of machine spindles which should be used with wheels of various sizes is given in Table 14. Bearing boxes must be of sufficient length to provide ample bearing surface.

**GRINDING WHEEL TROUBLES AND REMEDIES.**—The following is a summary of the common troubles of grinding wheel operation and the remedies therefor:

**Wheel Does Not Cut.**—1. If running too fast reduce speed of wheel. 2. Use a softer wheel. 3. Use a coarser wheel if finish is unimportant. 4. Be sure that abrasive is correct for material being ground.

**Wheel Wears Too Rapidly.**—1. If running too slow increase wheel speed. 2. Use harder wheel. 3. Use finer wheel. 4. Eliminate vibration in machine. 5. Reduce pressure of work on wheel.

**Wheel Does Not Give Good Finish** (precision grinding).—1. Dress wheel to a perfect cylinder. 2. Put smooth face on wheel with diamond. 3. Eliminate vibration of machine spindle. 4. Balance wheel if it is out of balance. 5. Use finer wheel. 6. Use shellac or rubber wheel.

**Wheel Loads.**—1. Increase speed if below that recommended. 2. Use coarser wheel. 3. Use softer wheel.

**Wheel Glazes.**—1. Reduce speed if above that recommended. 2. Use softer wheel. 3. Be sure correct abrasive is being used.

**Wheel Burns.**—See Wheel Does Not Cut.

**Wheel Does Not Hold Shape.**—See Wheel Wears too Rapidly.

## 4. PROTECTION DEVICES

Abrasive wheels should be guarded against breakage by protection hoods, protection flanges, protection bands or protection chucks.

**PROTECTION HOODS** provide the best protection and should be used wherever the work will permit. Few cases will be found where it is not possible to use some sort of hood. A properly designed hood, securely fastened to the base of the machine or floor, will retain the parts of a broken wheel and provides as nearly absolute protection to the operator as is possible. It is the only device affording protection against small particles of a broken wheel. Unless a hood is properly designed, however, it will give a false sense of security and thus may be worse than no protection at all. A hood should be strong enough to retain the parts of a broken wheel both at normal speed and high overspeed.

The A.S.A. Safety Code for the protection of abrasive wheels specifies the exposures of grinding wheel periphery shown in Figs. 4 to 9 for the various types of grinders. On bench and floor stands, exposure shall not exceed 90 deg., except in those cases where the nature of the work requires contact with the wheel below the horizontal, in which case the exposure shall not exceed 125 deg. See Fig. 5. Exposure in both cases shall begin not more than 65 deg. above the horizontal. For top grinding, *i.e.*, where the work is ground on the top of the wheel, the exposure shall be as small as practicable, with a maximum of 60 deg. Hoods shall be so constructed that the protecting member can be adjusted to the constantly decreasing diameter of the wheel by means of an adjustable

tongue or its equivalent so that the angular protection shown in Figs. 4 to 9 will be maintained throughout the life of the wheel, and the maximum distance between the wheel periphery and the adjustable member will not exceed 1/4 in. See Figs. 10 to 12. Table 15 gives the dimensions and material of the sides and peripheral members of hoods as fixed by the code. The code also presents drawings and dimensions of protection hoods constructed of structural steel.

**PROTECTION FLANGES.**—Tapered flanges when properly designed afford good protection and should be used where a hood is impracticable. They are used with tapered wheels, *i.e.*, wheels thicker at the hole than at the periphery. It is important that flanges be as large as possible and be changed as the wheel wears down close to the edge of the flange. Table 16, and Figs. 14 and 15 give dimensions of two satisfactory types of tapered flanges for wheels operating at a maximum peripheral speed of 6500 ft. per min. Fig. 16

(*Continued on page* 21–84)

and Table 17 give the dimensions of flanges for peripheral speeds from 6500 to 9500 ft. per min. Tapered flanges over 10 in. diam. should be made of steel. All other flanges may be made of cast iron, or material of equal strength.

**PROTECTION CHUCKS** are used with cylinders or ring wheels. Any chuck so designed that the jaws can support the wheel up to a point not further distant from the grinding edge than 1/4 of the height of the wheel is considered satisfactory. Although protection chucks do not furnish absolute protection, the wheels used in them usually are run at comparatively low speeds and the danger is not great.

**PROTECTION BANDS** for cup, cylinder and sectional ring wheels should be made of steel plate or wrought iron, and conform as closely as practical to the periphery of the wheel. Ends shall be so riveted, bolted or welded as to leave no projections on the inside of the band. Thickness and rivet spacing are as follows (A.S.A. Code, 1935):

| Wheel diam., in. | Under 8 | 8 to 24 | 25 to 30 |
|---|---|---|---|
| Thickness of band, in. | 1/16 | 1/8 | 1/4 |
| Min. diam. of rivets | 3/16 | 1/4 | 3/8 |
| Max. center distance of rivets | 3/4 | 1 | 1 1/4 |

If band is bolted or welded, strength of the connection should at least equal that of the above riveting.

## 5. GRINDING MACHINES

**TYPES OF GRINDING MACHINES.**—Grinding machines may be classified as cylindrical, internal, and surface grinders, based on the general character of the work. Each of these classes may be further subdivided according to special characteristics either of work or machine. The following paragraphs show the types of grinding machines most commonly used, together with their fields and limitations.

**External Cylindrical Grinding Machines** for general purpose grinding of cylindrical surfaces, as shafts, axles, etc., range from 6 to 16 in. swing. Standard sizes are 6 × 18 in.; 6 × 30 in.; 10 × 18 in.; 10 × 36 in.; 10 × 48 in.; 10 × 72 in.; 10 × 96 in.; 10 × 120 in.; 14 × 36 in.; 14 × 48 in.; 14 × 72 in.; 14 × 96 in.; 14 × 120 in.; 14 × 144 in.; 16 × 36 in.; 16 × 48 in.; 16 × 72 in.; 16 × 96 in.; 16 × 120 in.; 16 × 144 in.

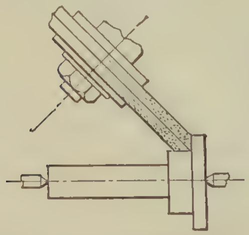

FIG. 17. Arrangement for Grinding Shoulders

Machines are built with hydraulic, mechanical or hand traverse or with all three, of both table and grinding wheel head. Grinding wheel and work drives usually are from separate motors through V-belts. For plunge cuts, *i.e.*, wheel fed perpendicular to work, steady rests and reciprocation of the wheel spindle are advisable. Cylinder grinders can be built to function automatically or semi-automatically, through a complete cycle, producing work ground within predetermined limits. They also may be fitted with attachments for cam, roll or crank-shaft grinding, although for regular production of this character, special machines are advisable. For grinding faces of shoulders and the adjacent cylindrical surfaces, cylindrical grinders are built with the wheel slide set at an angle of 45 deg. to the axis of the work, a V-shaped wheel being used. See Fig. 17.

**Roll Grinding Machines** are cylindrical grinders of 20, 24, 28, 32 and 36 in. swing by 96, 120, 144, 168, or 192 in. between centers. These are standard sizes. Special machines have been built up to 60 in. swing by 26 ft. long between centers. Roll grinding machines are built with the work traversing past a grinding wheel in a fixed position, or with the wheel traversing past the work. Rolls are crowned or concaved by moving the wheel, by appropriate mechanism, away from or toward the roll as the wheel traverses it.

**Cam and Shape Grinding Machines** are a special form of cylindrical grinder. In these machines, the work is rotated in a swinging member and is moved toward and away from the grinding wheel by means of a master cam in contact with a roller. The master cam is on the swinging member, the roller being fixed on the machine. Where the cams are integral with the cam shaft, they are carried on centers in the machine, one pair being in the master cam spindle and the other in a footstock mounted on the swinging member. Single cams are mounted in fixtures or on arbors carried by the master cam spindle. For high production, as automotive cam shafts, completely automatic machines are used. One type is a hydraulically-operated machine that successively grinds each cam to size, indexing after each grinding operation. When the last cam is ground, the table reverses, returns to the starting position and the work stops rotating. The wheel is trued automatically by a diamond, and its position changed to compensate for the truing. The table then stops in the loading position. This machine, made by the Norton Co., has a swing over the rocking bar of 6 in. Length of work between centers is 26, 30, 36 or 42 in.

**Centerless Grinders** are a special form of cylindrical grinder. Instead of the work being supported on centers, it is supported on a work rest, and held against a regulating wheel. See Fig. 18. By setting the regulating wheel at an angle to the grinding wheel, the former will act as a feeding device and will traverse the work past the grinding wheel. The regulating wheel is positively driven and its speed determines the rotational speed of the work. The centerless grinder operates on a diametral dimension instead of on a radial dimension of the work, as in grinders where the work is held on centers, and therefore under certain conditions it will remove double the amount of metal in a given time. On slender work, much higher grinding pressure can be used in the centerless machine, as the work is rigidly supported by the work rest and regulating wheel, whereas when supported on centers it will tend to spring away from the wheel under heavy pressure. Centerless grinders usually are built to take work up to 9 in. diam., and of any length.

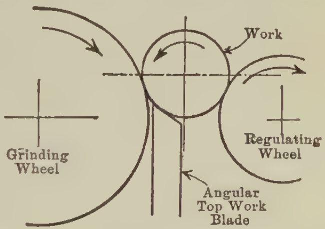

Fig. 18. Principle of Centerless Grinder

**Internal Cylindrical Grinders** comprise a reciprocating wheel head carrying a grinding wheel on a spindle long enough to reach to the bottom of the hole, and a work head in which the work can be rotated while in contact with the wheel, both carried on a suitable bed or frame, with provision for adjustment of both wheel and work. The field of the internal grinder is the finishing of holes in gears, bushings, bearings, etc., and the finishing of the inside surface of cylinders, as automotive cylinders. The cylinder grinder is a special form of internal grinder, and in one type the wheel head gives a planetary motion to the wheel spindle. H. L. Blood (*Trans.* A.S.M.E., MSP 54–1, 1932) describes an automatic internal grinder which rough grinds, trues the wheel, finish grinds the hole to size, runs the wheel out of the hole and brings all parts to the rest position. The range of capacity of internal grinders is holes from $^1/_4$ to 24 in. diam. and from 3 to 15 in. deep. Cylinder grinders are built to grind cylinders from 2 $^3/_8$ to 14 $^1/_2$ in. diam. by 11 to 18 in. long. Internal grinders are built by the Heald Machine Co., Worcester, Mass.

**Surface Grinders** are built in a variety of forms, *viz.*, with reciprocating or rotary tables, and with horizontal or vertical spindles. Grinding is done either with the face or side of the wheel, cup wheels being used in the latter case. Reciprocating tables usually are traversed hydraulically. In certain machines the rotating table can be set at an angle to permit grinding of concave or convex surfaces. Both direct motor drive and belt drive of grinding wheels are available. The capacity of the usual reciprocating table grinders ranges from work 6 × 18 in. to 14 × 60 in. Rotating-table surface grinders are built with tables up to 36 in. diam. Work usually is held on the table by magnetic chucks.

**Disc Grinders** are a form of surface grinder using abrasive discs mounted on a steel backing. The work is ground against the side of the disc. Single-spindle machines, with a disc on each end of the spindle, are built to use discs up to 40 in. diam. The work is supported on tables, equipped with either hand or power feed. The spindles are driven either direct from the motor, or through V-belts.

**The Double-spindle Disc Grinder** is a machine for grinding two parallel surfaces. It comprises, virtually, two single-end disc grinders, mounted on a common base, the wheel spindles being in line, with the wheels facing each other. The work, supported by a table, is fed in between the wheels, which are spaced the correct distance apart. Wheel spindles are driven direct from the motor or through V-belts. These machines are built in various sizes, with discs ranging from 15 to 72 in. diam., and with maximum opening between wheels ranging from 20 to 30 in.

**Face Grinders** are a form of surface grinder in which the work travels past the side of a wheel, carried on a horizontal spindle mounted at right angles to the line of travel of the work. The wheel grinds the vertical surface of the work at right angles to the surface of the table. The table is traversed hydraulically, and the wheel is driven by silent chain or V-belt. Work can be held by bolting to the table or to angle plates or by magnetic chucks. These machines are used for surface grinding and for the grinding of machine knives, shear blades, etc. Tables range from 22 to 27 in. wide and from 60 to 168 in. long.

**Universal Grinding Machines** are cylindrical grinders provided with a swiveling table, and swiveling headstocks and swiveling wheel slide. Their field is tool room work and manufacturing where a variety of parts in small lots are to be ground. They range in size from 12 to 16 in. swing and from 24 to 72 in. between centers.

**Tool and Cutter Grinding Machines** are designed primarily for grinding of reamers, milling cutters, etc. In their simplest form they comprise a motor-driven grinding wheel and a pair of centers upon which the work is mounted, carried on a table that can be traversed past the wheel by hand. More elaborate machines comprise a power-operated swiveling table, a power-driven headstock to permit the machine to be used for cylindrical grinding, and attachments that permit of internal grinding and various forms of surface grinding. The capacity of tool grinders ranges usually up to 12 in. diam. by 30 to 36 in. between centers.

* Diam. of cylindrical work; diam. of holes, internal grinding; width of surface, flat work. † Each motor, 2-wheel machine. ‡ Sectional wheel—dimension given is width of rim or working face. § Width of working face or rim of cup wheel. ¶ Segmental wheel. ‖ Minimum diam. of hole; max. outside diam. of work, 3 in.

**HORSEPOWER REQUIRED FOR GRINDING** will vary directly with the quantity of metal removed. R. E. W. Harrison gives (*Trans.* A.S.M.E., MSP 51–18, 1929) the relation between horsepower and metal removal in centerless or controlled center cylindrical grinders as follows:

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Horsepower at grinding wheel spindle ....... | 5 | 10 | 15 | 20 | 25 | 30 | 35 | 40 |
| Metal removal capacity, cu. in. per min ..... | $\frac{1}{2}$ | 1 | $1\frac{1}{2}$ | 2 | $2\frac{1}{2}$ | 3 | $3\frac{1}{2}$ | 4 |

Table 18 shows the size of motors fitted to various types of grinders as built by several manufacturers.

**GRINDSTONES** are natural sandstones, in which silicon oxide, $SiO_2$ comprises the abrasive medium. Formerly, widely used for sharpening tools, finishing of cutlery, snagging of castings, etc., they have largely been displaced by vitrified abrasive wheels and by polishing wheels.

Surface speed of grindstones ranges from 500 to 600 ft. per min. for grinding woodworking tools, from 800 to 1000 ft. per min. for metal working tools, and from 1500 to 3500 ft. per min. for polishing operations. The limiting speed is the strength of the stone, which is variable. Wet stones may have only 50% of the strength they possess when dry. Also, stones from the same quarry may vary in strength. In general, 3400 ft. per min. surface speed should not be exceeded, and 2500 ft. per min. is a safer limit. Revolutions per minute corresponding to 3400 and 2500 ft. per min. for various sizes of grindstones are as follows:

| | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Diam., in ................ | 36 | 42 | 48 | 54 | 60 | 66 | 72 | 78 | 84 | 90 | 96 |
| R.p.m. (2500 ft. per min.) .. | 265 | 227 | 199 | 177 | 159 | 145 | 133 | 123 | 114 | 106 | 99 |
| R.p.m. (3400 " " " ) .. | 360 | 309 | 270 | 240 | 216 | 197 | 180 | 166 | 154 | 144 | 135 |

Grindstones should not be mounted on square shafts as has been common practice. The wooden wedges driven between the shaft and the stone, will, if driven too tightly, or when swollen when wet, tend to start a crack in the corners of the square hole in the stone. This crack gradually extends until the stone ruptures. After the stone has been centered properly on a round shaft, the space between it and the shaft should be filled with lead or cement. Large flanges should be used to support the stone, separated from it by pads of leather, rubber or paper to compensate for irregularity in the mating surfaces.

When grindstones are used to produce smooth surfaces in manufacturing operations, they frequently are hacked around the circumference in a herringbone pattern with cuts about $1\frac{1}{4}$ in. apart to make the stone cut faster. The operation is repeated whenever the hacked surfaces are worn smooth. Grindstones never should be allowed to stand in water when not in use. They will absorb water which will decrease the strength, and also throw the stone out of balance.

## 6. LAPPING AND HONING

**LAPPING** is used to produce exceedingly smooth and highly accurate surfaces, either flat or cylindrical. A lap, usually of cast iron, charged with fine abrasive, is rubbed against the surface of the work either by hand or by machine. Since about 1930 a lap consisting of fine abrasives bonded together has been used in many instances to replace the metal lap charged with loose abrasive. Laps are used with kerosene and lard oil lubricants.

Formerly limited in use to the production of precision surfaces in gages and measuring instruments, lapping has since 1930 been generally adopted as a production process in many industries, particularly the automotive. In the latter, it is used for the finishing of crank-pins, bearings, piston rings, ball-bearing races, valve tappets and other wearing parts. Lapping tolerances of 0.000 05 in. in diameter and 0.000 025 in. in straightness and roundness are possible of attainment.

Sydney Player describes (*Trans.* A.S.M.E. MSP 52–14, 1930) the lapping of plug gages 0.875 in. diameter ±0.000 02 in. Two lapping operations were required. The grinding limit was +0.000 15 to +0.0003 in. Rough lapping with M–304 American Optical emery brought the gages to within 0.000 05 in. of finished size. For finish lapping, the laps were hand scraped and worked together with levigated alumina until the surface of the laps were mirror finished. The author of this paper also describes lapping, in lapping machines, of piston-pins to limits of 0.0001 in. for straightness and roundness, the production being 500 pins per hour.

**Lapping Machines** consist essentially of a pair of laps which may be rotated independently of each other and in opposite directions if desired. The work to be lapped, which may be either cylindrical or flat, is carried in work holders, which positions the work between the two laps, and at the same time moves it between the lap faces with a planetary motion in a constantly varying line of travel relative to the lap surfaces. For cylindrical work, the pieces are carried in the work holder at an angle to radial lines. An eccentric motion imparted to the work holder which, in conjunction with the non-radial position of the work, causes all portions of the surface to come in contact with the laps and a true lapped surface is produced. The capacity of lapping machines ranges up to 3 in. in thickness or diameter by 6 in. long.

The centerless lapping machine is similar in its principle of operation and in general construction to the centerless grinding machine. The lapping is done by wheels of finely divided abrasive suitably bonded. The lapping wheel is driven at a speed of 150, 195 or 225 r.p.m. Through-feed work from $^1/_2$ to 3 in. diameter and of any length can be lapped in the centerless machine. By means of special equipment, work which cannot be passed transversely through the machine can be lapped up to 6 in. diameter and 15 in. long.

**Manufacturers.**—Lapping machines are built by Cincinnati Grinders, Incorporated, Cincinnati, Ohio; Norton Co., Worcester, Mass.

**HONING** is a term applied to the lapping of the interior of cylindrical bores. It is used for the accurate finishing of automotive cylinders, compressor cylinders, cylinders in hydraulic and refrigeration units, bushings, bearings, connecting rods, etc. It consists essentially in the passage of a honing stone or stones in an axial direction through the bore, the hone being rotated at the same time. Tolerances of 0.0005 to 0.0002 in. are commercially possible. J. W. Hindes and J. G. Young (*Trans.* A.S.M.E. MSP 53–13, 1931) state that a ratio of about 1 to 3 of reciprocation to rotation speed gives the most satisfactory results (65–70 surface ft. per min. reciprocation, 200 ft. per min. rotation). If the hone is hard and tends to glaze, this condition can be corrected by increasing the ratio of reciprocating to rotating speed.

The hone usually is a form of expanding segmental wheel, whose surface is formed by a series of abrasive stones carried in a holder. Means are provided to expand the stones to the wall of the cylinder being ground, and to hold them against it under pressure, while the hone is reciprocated and rotated. Wear of the stones is compensated by floating cones in the holders which feed the stones outward and maintain them in parallelism.

J. A. Carlin (*Auto. Ind.*, Dec. 9, 1933) describes a method of honing blind end bores, by shifting the center of pressure on the abrasive stones toward the blind end to compensate for the loss of abrasive effect resulting from inability of the hone to overrun the end of the cylinder. J. E. Kline (*Iron Age*, April 5, 1934) illustrates a fixture used for precision finishing by honing connecting rod crank-pin bores.

**Lubricant.**—Kerosene is generally used as a coolant and lubricant in honing cast iron and other metals. Turpentine gives a freer cutting action on bronze and brass. Water is unsatisfactory.

**Manufacturers.**—Honing machines are made by Barnes Drill Co., Rockford, Ill., Hutto Engineering Co., Detroit, Micromatic Hone Co., Detroit.

## 7. POLISHING AND BUFFING

### Polishing

Polishing is the removal of metal by means of a flexible wheel coated with abrasive. The wheels are made of various materials as described below. The abrasive may be any of the many forms of manufactured abrasives or natural emery. It is held to the face of the wheel by means of an adhesive, usually glue.

**POLISHING WHEELS.**—The earliest form of polishing wheel was a wood disc with a strap of leather fastened to its circumference. This form of wheel has practically disappeared. Polishing wheels in common use are made of buff sections (see below) sewed or glued together to make a wheel of the desired face, of discs of canvas sewed or glued together, or of discs of leather, sheepskin, walrus hide, or similar material. The compress wheel is made of blocks of canvas, leather, sheepskin, paper and other materials, compressed to the required density. The field of application and the characteristic of the several types of wheel are described below.

**Clothflex Wheels** is a general term applied to polishing wheels built of buff sections. The density, *i.e.*, resiliency, of the wheel is determined by the sewing of the buff sections and by the extent of the area of the buff that is glued. Buff sections in which the rows of concentric or spiral sewing are spaced closely, say $^1/_4$ in. apart, and which are glued to the circumference of the buff form the densest clothflex wheel. Wheels of lesser density can be made of sections with wider spaced sewing, say from $^3/_8$ up to $^3/_4$ in., the glue being stopped between 1 to 4 in. from the periphery of the wheel. A wheel that is not glued to its periphery, however, has a tendency to separate at the joints between the buff sections and to leave streaks on the surface of the work. Variation in density is best obtained by wider spacing of the sewing of the buff sections. The least dense type of clothflex wheel is obtained by omitting the glue entirely and holding the buff sections together by several rows of hand sewing.

Clothflex wheels are made both of full disc buffs and sewed piece buffs. Both types are made with cloth of different weaves and each type and weave has its special field of service. Manufacturers of polishing wheels should be consulted on the selection of the grade and construction of wheel that is best adapted to a particular class of work.

Polishing wheels made of sewed piece buffs are used on plumbing supplies, such as faucets, tubular plumbing goods, and on brass, iron, and copper castings with contoured surfaces, and on steel stampings. They may be used on work where the corners are rounded and where it is not necessary to maintain sharp edges. They are not adapted to work where the edges of openings must be held square or where corners must not be rounded over.

The full-disc polishing wheel, *i.e.* made of full disc buff sections, is adapted to use on automatic machines and to work where perfect wheel balance must be maintained. Any desired density of full disc clothflex wheel may be obtained by building it of packed buff sections, that is, sections with discs of smaller diameter in between the buff discs.

**Disc Canvas Wheels** are made of discs of canvas sewed or glued together either singly or in sections of two or three discs. Density can be varied in the same manner as with clothflex wheels by variations in sewing and gluing. The disc canvas wheel is adapted to heavier and rougher work than the clothflex wheel, and is widely used for polishing automobile bumpers, mould boards of plows, harrow discs, etc. It is especially adapted to breaking through scale and to removing deep pits or irregularities in the surface of the work. The disc canvas wheel often is used for roughing with the coarser abrasive grains, finishing being done by a clothflex or a compress wheel coated with finer grain.

**Compress Wheels.**—The process of making a compress wheel consists in assembling blocks of the wheel material into a ring about $1\ ^1/_2$ times the final diameter of the wheel. The assembled ring then is forced through a hollow cone about 3 ft. long, which compresses it radially and circumferentially to the required diameter and discharges it into a cast-iron ring which retains it until it is assembled into the completed wheel. Grooves are cut in the sides of the ring of compressed material into which are dovetailed the edges of flanged steel side plates mounted on a hub. The side plates are riveted together and retain the compressed material in form and place. The assembled wheel then is removed from the cast-iron retaining ring and turned to final diameter in a lathe.

Canvas is the material most widely used in compress wheels. Other materials are leather, sheepskin, felt, walrus hide and paper. Each material has its specific use and produces a different character of surface. Wheel manufacturers should be consulted concerning special applications, and also in regard to the density and cushion to be used for various classes of work.

The density of a compress wheel can be varied over a wide range by varying the number of blocks of material that are assembled into the wheel. The cushion, *i.e.* the distance that the material projects above the side plates, also can be varied within certain limits. Two-inch cushion is the most commonly used, but 3-in. cushion is used where a particularly yielding wheel is desired, and 1-in. cushion where the wheel is required to be rigid.

In the compress canvas wheel, seven densities are regularly manufactured ranging from super-soft to super-hard. The softer wheels are used for contour work or work where the surface may vary more or less from established dimensions and a yielding wheel is necessary to adapt itself to the surface. In general, the softer densities are used in the cutlery trade, on double-header machines, for finishing large knives and on other work where the wheel must flex to cover the surface. Soft wheels should not be used under heavy pressure, as the resulting flexure of the fabric will generate sufficient heat to char the fabric.

The medium density compress canvas wheel is a general all-around wheel largely used as a finishing wheel on such work as automobile bumper bars, sewing machine parts, hardware, automobile accessories and similar work. It frequently is made with formed faces to fit contoured work. The harder densities of wheels are widely used in the cutlery trade for glazing cutlery and table knives. The super-hard density is used for the honing of razor blades. The selection of the proper density is highly important, a difference of even one-half grade in density often being the cause of success or failure of a wheel on a given job.

The compress leather wheel is used where edges and corners are to be held square and where holes are present in the work. These wheels are largely used to polish flat-iron sole plates, both for roughing and finishing, excepting the final operation which is performed with a compress canvas wheel. Compress leather wheels also are used in the cutlery trade for the finishing of knife blades.

Compress walrus and compress sheepskin wheels are used in the cutlery trade, the latter wheel giving a fine surface and good color.

**PREPARATION OF POLISHING WHEELS.**—Various adhesives have been used to hold the abrasive grain on polishing wheels. High-grade hide glue, however, has proven the most satisfactory, as it is the only adhesive that seems to possess all the characteristics required in a polishing wheel adhesive, *i.e.* strength, toughness, flexibility and heat resistance.

The wheel, if new, should first be sized with glue, as should old wheels if the abrasive head has been completely removed. The sizing solution is one part glue to 12 parts water by weight. It should be thoroughly brushed into the surface of the wheel and allowed to dry for a period of 24 hours. Narrow-faced disc wheels should be dried between flat weighted plates to avoid warping.

The abrasive head is applied by thoroughly coating the face of the wheel with a solution of glue of the proper density and immediately rolling the wheel with a firm downward pressure in a trough filled with abrasive. The length of the trough should be somewhat longer than the circumference of the largest wheel to be coated. The practice of using short troughs and bumping the wheel into the abrasive while turning it on an arbor cannot be recommended. The head thus produced is uneven and tends to throw the wheel out of balance. A second coat of abrasive should be applied after an interval of from 20 to 30 minutes. The wheels should be at a temperature of from 75° to 90° F. when the glue is applied. After coating with abrasive they should be dried for not less than 48 hours at a temperature not to exceed 75° F. Shorter drying times or higher temperatures will shorten the life of the wheel head and increase the cost by the useless expenditure of abrasive and the increased labor for setting up. Where a large number of polishing wheels are used daily, air conditioning of the drying room will be profitable. The best conditions for drying are a temperature range of 70° to 75° F. and relative humidity of 50 to 55%.

**Preparation of the Glue.**—Correct handling of the glue is the most important factor in economical polishing. Density of the glue, *i.e.* proportion of water to dry glue should be varied in accordance with the size of the grain to be applied. Table 19 shows proportions of water and glue found to be best for the various sizes of abrasive grain. The glue should be soaked in cold water from three to four hours, and after all the water is absorbed the glue should be melted at a temperature of 150 to 160° F. It then will be at about its temperature of maximum strength (134° F.) when the wheel is rolled in the abrasive. Glue temperature should not exceed 160° F. since it rapidly loses strength at elevated temperatures. Glue deteriorates in strength also by standing under heat. Therefore, no more glue should be mixed and melted at one time than will suffice for about 4 hours work. It is advisable to melt glue in thermostatically-controlled electrically-heated glue pots, which will maintain the temperature within ± 2° F. As glue is highly susceptible to deterioration from organic matter, glue pots should be thoroughly cleaned after use, and the use of remelted glue absolutely prohibited. Glue brushes should be soaked in a 5% solution of carbolic acid when not in use. Only distilled water should be used in the preparation of glue.

**WHEEL BALANCE.**—All polishing wheels should be carefully balanced before use. Unbalanced wheels produce poor work, have short life of wheel head and increase the cost of production both by reason of the extra effort required to produce good surfaces and the lower production resulting from increased fatigue of the operator on hand work. On automatic machines good work is almost impossible with unbalanced wheels. Balancing is performed by mounting the wheels on an arbor and placing them on balancing ways. Clothflex and disc canvas wheels are balanced by tacking pieces of lead on the side of the wheel. Compress wheels are balanced by inserting lead weights in balancing tubes which are built into the wheel. This type of wheel is susceptible to much more accurate balance than disc wheels. For high precision work, dynamic balance of wheels is advisable, and in some cases imperative.

**APPLICATIONS OF POLISHING WHEELS.**—It is impossible to lay down rules covering all cases of the application of polishing wheels. The wide range of variables

**Table 19.—Proportions of Glue and Water for Setting Up Polishing Wheels**

| Size of abrasive grain | 36 | 46 | 60 | 90 | 120 | 150 |
|---|---|---|---|---|---|---|
| Percentage of dry glue | 45 | 40 | 35 | 33 | 30 | 25 |
| Lb. of water per lb. of glue | 1.22 | 1.50 | 1.86 | 2.30 | 2.50 | 3.00 |
| Qt. of water per lb. of glue | 0.59 | 0.72 | 0.90 | 0.98 | 1.00 | 1.40 |

encountered both in hand lathes and automatic machines, the wide variety of materials polished, and the constantly varying character of the work surface, set up conditions that are peculiar to the individual job. Wheel speeds that are correct for one set of conditions would be highly inefficient under another set of conditions. Wheel pressure that is necessary for one class of work would ruin another class. Work speed in relation to wheel speed must be varied in accordance with the character of the material, the shape of the work and the degree of finish desired, particularly with automatic machines. Table 20 gives data of typical polishing jobs that will serve as a guide in the application of polishing wheels.

* CC = Compress canvas. CF = Clothflex. CL = Compress Leather. CP = Compress paper. DC = Disc canvas.

† See paragraph Polishing Wheel Speeds.

Note 1.—Compress canvas is used to avoid streaking the work. The soft density permits the work to embed itself in the wheel, which thus covers the irregular contour.

Note 2.—A clothflex wheel is used because the shape of the work requires sidewise flexibility in the wheel. The face of the wheel is formed to the radius of the corner.

Note 3.—The face of the wheel is formed to fit the outline of the faucet. The clothflex wheel is used on account of its flexibility and relative cheapness for a job whose volume is not sufficient to warrant the increased expense of a compress wheel.

Note 4.—Compress leather or hard compress canvas is used where a square edge must be preserved, or where sharp corners are to be polished, or a truly plane surface is to be maintained. Such wheels are rigid and yet resilient.

Note 5.—The compress canvas wheel will produce a color on the work that cannot be obtained by the compress leather wheel.

Note 6.—Compress canvas can be formed to the contour of the work and will hold its shape indefinitely. The soft density enables the wheel to cover the entire surface to be polished.

Note 7.—This wheel operates without abrasive glued to the face. Loose abrasive, slightly moistened with oil, is thrown between the wheel and the work. The wheel is formed to the contour of the cup. The operation is known as sand buffing, and compress leather wheels are always used.

Note 8.—A superhard wheel is required in order to hold the surface uniformly flat and to avoid the formation of waves and ridges.

Note 9.—A supersoft wheel will crush sufficiently to conform to the slight irregularities in contour of the work. This avoids using a second formed wheel to finish the irregular surface.

Note 10.—This operation is performed in a double-header machine. The wheels must be soft enough and flexible enough to cover the entire blade surface from heel to edge. The soft density and deep cushion fulfill these requirements.

Note 11.—A disc canvas wheel is best suited to rough work on an irregular surface.

Note 12.—An extremely hard wheel is necessary to maintain contour on a narrow edge and to prevent rounding of the edges.

**POLISHING WHEEL SPEEDS.**—A surface speed of 7500 ft. per min. has commonly been used for polishing wheels working on steel, iron or brass, and due to long usage has been regarded as the most efficient speed. The figures for surface speed given in Table 20 are the speeds that actually were used on commercial jobs. Some recent research, however, has demonstrated that the commonly accepted surface speed of 7500 ft. per min, is not necessarily the most efficient speed. A speed of 6700 ft. per min., polishing medium steel showed an improvement of about 15% from the standpoint both of metal removal and time consumed. Similar results were obtained with a speed of about 7000 ft. when polishing cast iron. Investigation has not (1937) been sufficiently detailed to determine whether or not these two speeds are the most efficient. It, therefore, is advisable for manufacturers polishing large quantities of metal to conduct experiments to determine the most efficient speeds for their particular conditions.

**ABRASIVES.**—The type and size of abrasive used on polishing wheels depends on the material polished and the finish desired. Turkish emery formerly was used almost exclusively. It has been displaced by the manufactured abrasives, except as a finishing abrasive where high color is desired. For steel and brass the aluminum oxide abrasives give the highest cutting efficiency and longest wheel life. For cast iron, a silicon carbide abrasive should be used.

The size of abrasive grain to be used depends on the initial character of the surface and the finish to be produced. The first wheel should be coated with abrasive that will cut down to the bottom of the deepest pits and break through scale. The second wheel should be coated with a finer abrasive that will cut out the grain scratches made by the coarser wheel. The next wheel should have still finer grain, and so on until the desired surface has been produced. The final wheels should be greased with oil or tallow to modify the cut, and to produce a more lustrous surface.

A common sequence of grain sizes for the hand lathe polishing steel is: First wheel, No. 60 or 90; second wheel, No. 90 or 120; third wheel, No. 120 or 150. If deep pits are present in the work, it may be necessary to use a coarser abrasive on the first wheel, say No. 46. It should be remembered, however, that each wheel must remove the grain scratches of the preceding wheel and it may be more economical to use a finer wheel for a longer time to remove pits, than to spend time removing coarse grain scratches. Highly polished steel is finished with a sequence of grain sizes of Nos. 60, 90, 120, 180, and 220. All the wheels finer than No. 90 should be oiled or greased. The sequence of grains may be extended even farther to produce mirror-like, scratchless surfaces. Rolls for copper and brass rolling mills have been finished with a final wheel coated with levigated alumina, which is about equivalent to a grain size of No. 640.

**DESCALING.**—The scale on castings or forgings imposes a heavy burden on the initial polishing wheels, which must break down this scale. Some scales are so hard as to absolutely resist the action of the wheel. Such scales should be removed by pickling or by one of the electrochemical processes of descaling. For continuous production, descaling will soon pay for itself in increased wheel life and decreased number of wheels necessary to produce the desired surface.

**Pickling Solutions.**—Castings may be pickled in a solution of sulphuric acid, diluted with water to a specific gravity of 25 deg. Baumé. Forgings should be pickled in a solution of sulphuric acid and water of a specific gravity of 30 deg. Baumé, for from 3 to 12 hours. After pickling, forgings and castings should be washed with hot water to remove the sand and acid. A disadvantage of acid pickling is the tendency to etch pits still deeper, thus adding to the work of the polishing wheels.

**Bullard-Dunn Process.**—This process, patented by the Bullard Co., Bridgeport, Conn., is a simple, rapid and inexpensive electrochemical method of removing scale and oxides from the surface of metals. It is particularly adapted to descaling iron and steel, including the stainless steels. The characteristic feature is a continuous, non-porous metal film electro-deposited on the work simultaneously with the scale and oxide removal. The film prevents damage to the work by protecting it from surface pitting and etching. While it can be removed easily and completely, it is usually advantageous to permit it to remain on the work. The equipment used is an ordinary electroplating tank, using direct current of 6 volts or less. The current density is about 60 amperes per square foot of exposed surface. Anodes of whatever metal is desired for the film are used, lead and tin being the most common. The film deposited is on the order of 0.000 001 in. thick. For large output, automatic conveyors are used in the tanks; manual operation of tanks is satisfactory for smaller outputs. In operation, the film is deposited instantaneously on the removal of the scale, and inhibits further action. No allowance, therefore, need be made in basic dimensions to compensate for dimensional losses. Scale is completely removed from bottoms of threads, from cracks, crevices and internal surfaces. The removal of scale is accomplished rapidly.

## Buffing

Buffing consists in leveling off minute projections on the surface of metal, and in producing a sheen or luster on the surface so prepared. The first operation is termed *cutting down* and the second *coloring*. The work is performed with a buffing wheel which is composed of a number of circular discs of cloth mounted on an arbor and rotated at high speed. Buffs or buffing wheels are made in several forms each of which has its particular field of application.

**BUFFING WHEELS.**—Buffing wheels are made by assembling on an arbor a sufficient number of *buff sections* to form a wheel of the requisite width of face. The various forms of buff that are used are: 1. Full disc buffs, which may be either *loose* or *sewed*. 2. Sewed piece buffs, which always are sewed. 3. Some form of patented folded buff.

Buff material usually, but not always, is cotton sheeting, bleached or unbleached. The most widely used grade of sheeting has a warp of 64 threads per inch and a filling of 68 threads. It commonly is known as 64 × 68 cloth. Another widely used fabric is woven 84 × 92. Buffs made of this fabric are harder and will stand rougher usage than those made of 64 × 68 fabric. They generally are used for the cutting down operation, the 64 × 68 buff generally being used for coloring. Buffs made of bleached material are harder than those of unbleached fabric.

**Full Disc Buffs** are made of complete discs of the fabric and are assembled in *sections*, usually of 20 plies of fabric. The loose buff is sewed with three or four closely spaced rows of sewing around the hole to hold the discs together. The sewed buff in addition to the sewing around the center hole is sewed with concentric or spiral rows of sewing, spaced at any desired interval, from the center hole to the periphery. The wider the spacing of this sewing the more flexible and yielding is the buff. Other forms of sewing sometimes are employed, as radial sewing in which the sewing extends on radial lines from the center to the periphery; tangent sewing in which the sewing is tangent to a circle of about 3-in. diameter, and extends to the periphery of the buff; various forms of geometric patterns. While these special buffs have some fields of application, the concentric or spirally sewed buff generally is satisfactory for most work.

The 64 × 68 loose buff is used for coloring soft nickel, brass, and cast iron. When sewed it may be used for cutting down copper, soft brass, zinc and similar metals on hand lathes. The 84 × 92 buff both in sewed and loose form is used to cut down copper, brass, German silver and heavy nickel plate on bumper bars, builders' hardware, etc. For chromium plate, it should be sewed.

**Sewed Piece Buffs.**—The sewed piece buff is built up of more or less irregularly shaped pieces held between two full discs of fabric and sewed from the center hole to the periphery with spiral sewing. The same grades of fabric are used in sewed piece buffs of the better grades as in the full disc buffs. Many of the cheaper buffs of this character contain much coarser and flimsier fabric. The better grades of sewed piece buffs are built of relatively large pieces whose area ranges from $^1/_2$ to $^1/_4$ the area of the full disc. The cheaper grades contain smaller pieces which may range down to 5% of the area of the disc. The buffs with the large pieces are more durable and are better balanced than those built of small pieces, and from an operating cost standpoint, are much more economical than the others. It is impossible to determine the size of the pieces used in building a sewed piece buff without destroying the buff, and buff users should not be misled by low prices. Where sewed piece buffs are purchased in large quantities, it is wise to procure them only from manufacturers who have established reputations for quality. The sewed piece buff costs less than the full disc, and for many buffing operations is equally satisfactory.

Sewed piece buffs are largely used for cutting down cast plumbing goods, brass stampings, brass tubular goods, and aluminum castings.

**Folded Buffs.**—Folded buffs consist of full discs folded and assembled in various ways to form pockets which then are assembled to form a complete circle and are sewed either as a loose buff or as a spirally sewed buff. These buffs are used both for cutting down and for coloring. Their action is somewhat different from that of the loose or the sewed piece buff, in that the edge of the fabric passes across the work at an angle to the plane of the buff wheel. Buff marks on the work which are produced by each separate layer of fabric in the other types of buff thus are avoided. Another advantage of the folded buff is that the pockets tend to trap air, which has a cooling effect on the buff surface. Folded buffs are relatively more expensive than any other type, because of the large amount of hand labor required in their manufacture.

**BUFF VENTILATION.**—Buffs continuously operating under heavy pressure must be ventilated in order to dissipate the heat generated. Without adequate ventilation the buff may char or even be set afire. Folded buffs have provision for ventilation inherent in their construction. Full disc buffs may be ventilated by the process known as *packing*. This consists in assembling one or two discs of smaller diameter than the buff disc between each pair of buff discs, or at such intervals as may be necessary, depending upon the severity of the work. Sewed piece buffs can be ventilated by inserting a few discs of fabric or washers of felt or leather between each section. Packed buffs should be oscillated axially in relation to the work in order to avoid distinct streaks at the points where the discs or sections are separated by the packing.

**SPEED OF BUFFS.**—The surface speed at which a buff should operate depends on the type of metal being buffed. Table 21 shows the speeds commonly used with various metals and various grades of buffs. In general, higher speeds are used for cutting down than for coloring with the copper bearing metals.

Since a buff wears down in use, its peripheral speed constantly decreases. Provision should be made to maintain the peripheral speed fairly constant either by the provision of a variable speed drive or by changing the buff to a machine of higher spindle speed for each decrease of 2 in. diameter.

**PRESSURE AND HORSEPOWER FOR BUFFING.**—The effectiveness of buffing depends largely on the pressure of the wheel on the work. Increasing the pressure increases the rapidity of cutting, but at the same time increases the liability of cutting through the plating on plated articles. Definite rules cannot be given since the pressure that safely can be applied depends on the hardness of the plating and its thickness. A heavy coat of hard nickel can withstand much greater pressure than a thin coat of soft nickel. The horsepower required for buffing is a function of the pressure of the wheel on the work. In general, for buffing nickel plate on steel on hand lathes 3 to 5 Hp. at the buff is the usual practice. For heavy work, such as automobile bumper bars, hand lathes usually are equipped with 10 to 15 Hp. motors.

Brass requires considerably more horsepower for buffing than does steel or nickel. Experiments made by the author indicated that a pressure of 15 lb. per inch of width is required for cutting down sheet brass, and 10 lb. per inch of width is required for coloring. Table 22 shows the power required for cutting down and coloring sheet brass. The figures are based on finishing the brass at a work speed of 18 lineal ft. per min. in an automatic machine.

**BUFFING COMPOSITIONS.**—The following compositions are adapted to the different varieties of work: For cutting down brass, bronze and Britannia metal preparatory to plating, tripoli; for smooth surfaces on nickel and brass, crocus; for coloring brass, copper, nickel, bronze, German silver, etc., either in solid or plated metal, White Diamond XXX composition; for chased or embossed parts, or for cutting down silver-plated pieces which are afterward to be colored with rouge and alcohol, White Diamond XXXX composition is used; for nickel-plated pieces with a high luster, Vienna lime. Where rapid, sharp, even cutting is desired, emery cake is used. Chandelier rouge is used to produce a deep color on brass and bronze parts. Chromium oxide is used for chromium plated articles and stainless steel.

## Polishing and Buffing Machinery

**Hand Lathes.**—For irregularly shaped pieces, or where work is performed in relatively small lots, the hand lathe is almost universally used both for polishing and buffing. These

are built in a wide variety of sizes and styles ranging from a simple cupola jack to large double-spindle machines driven by independent motors and built with the precision of high-grade machine tools. A common type of motor-driven machine is the single spindle machine with the motor armature on the spindle. The spindle projects at either end to form arbors for the polishing or buffing wheels. Many motor-driven lathes are available with the motor mounted in the base, driving the spindle through flat- or V-belt drives. These machines have the advantage, in common with the plain belt-driven machine, of the possibility of changing spindle speed by changing the driving or driven pulley. The better grades of polishing and buffing lathes are built with ball-bearing spindles.

Points to be considered in the selection of a lathe for polishing and buffing are: Adequate diameter of spindle between bearings and adequate diameter of wheel arbors; adequate overhang of wheels beyond the base to permit the handling of long and irregularly shaped pieces without interference with the operator working at the wheel at the other end of the spindle; correct height of spindle above the floor, since a few inches difference in height will engender fatigue and decrease production; motor of ample size to handle the heaviest work which may come to the lathe.

Lathe arbors commonly have been made 1 in. to 1 $^1/_4$ in. diameter. This is adequate for the usual range of buffing jobs, but is too light for many polishing jobs particularly if wide, heavy compress wheels are used. Arbors of 1 $^1/_2$ in. diameter will prove more satisfactory for the general run of polishing, and 1 $^3/_4$ in. is better for severe duty like the polishing of automobile bumper bars where the wheel is subjected to heavy pressure.

Motors for the general run of light work should not be less than 5 Hp. For medium duty work, motors of 7 $^1/_2$ to 10 Hp. will prove satisfactory, while for the heaviest class of work, 15 to 20 Hp. motors should be used. It is economy to install more, rather than less, horsepower than is actually needed both on polishing and buffing lathes.

**AUTOMATIC AND SEMI-AUTOMATIC MACHINES.**—For long runs of similar work, automatic or semi-automatic polishing and buffing machines are advisable. They are economical of labor, have high capacity and produce uniform work. In one instance, automatic equipment reduced the number employed on a given line of work from 31 to 5 operators, increasing production at the same time. Automatic machines for automobile bumpers have been built with an output of upwards of 300 sets of bumpers per hour. Automatic machines may be divided generally into three classes, straight-line machines, multiple-head machines, and contour machines.

**Straight-line Machines** comprise essentially a conveyor on which the work is carried in appropriate chucks or holders underneath a series of polishing wheels, successively coated with the various sizes of grain necessary to obtain the desired finish. The wheels are arranged to float, either on an arm oscillating vertically on a horizontal shaft, or between vertical guides. Each wheel is driven by an independent motor, direct-connected to the wheel spindle or driving the wheel spindle through V-belts. The conveyor is driven by an independent motor. The more common form of conveyor is a belt, although various other forms embodying roller chain, or other construction, have been built. The conveyor usually is driven through a speed changing device at speeds ranging from 15 to 35 ft. per min.

The use of floating wheels permits the straight-line machine to polish and buff work that is irregular in contour, for example, automobile bumper bars, which are offset, *i.e.* all longitudinal elements not in the same straight line. The wheels strike the lowest part of the bar as it moves under them and float upwards as the bar moves, following the curve of the bar. By the use of wheels of the proper contour the rise of the wheel will bring a different portion of its face into contact with the bar at the offset, thus polishing the entire surface. By a study of wheel forms, wheel pressures and work speeds, many irregularly shaped forms can be finished in straight-line machines. They are widely used not only for automobile bumpers, but for flat-iron sole plates, automobile door hinges, pliers, open-end wrenches, typewriter and adding machine parts, washing and ironing machine parts, electrical appliances, etc.

Motor horsepower ranges from 5 Hp. per spindle for light work such as typewriter and adding-machine parts, to 20 Hp. on automobile bumpers. Conveyor motor horsepower ranges from 2 $^1/_2$ on short machines for light work up to 10 or 15 Hp. for 16- or 20-wheel bumper machines.

**Multiple-head Machines.**—Multiple-head machines are used principally for the finishing of circular work. In their simplest form they consist of a head carrying two spindles on which chucks are mounted to hold the work. The head is indexed by hand to bring the work on each spindle in contact with the polishing or buffing wheel. The spindle in the working position is rotated by a small motor mounted on the machine. The idle spindle is unloaded and reloaded during the operating time of the working spindle. Other forms of machines have heads carrying from 4 to 6 spindles which automatically are indexed into contact with the polishing or buffing wheels at predetermined intervals. Other forms of this type of machine are provided with mechanisms to oscillate the head in a direction parallel to the face of the wheel, the work spindle being rotated at the same time. This enables long work to be finished with a narrow wheel. Machines of the foregoing types usually are built separate from the polishing wheel. In general, they are relatively light machines which easily can be moved into position alongside of a hand lathe and removed when the work is completed or the lathe is needed for other purposes. Larger forms, however, have the polishing or buffing wheels incorporated in the machine.

Other forms of multiple-head machines comprise horizontal tables carrying from 4 to 6, or even more, work chucks. These are indexed successively under a series of polishing or buffing wheels. The number of wheels is one or two less than the number of chucks, thus providing a station for loading and unloading. The polishing or buffing wheels either are integral with the machines or carried on separate stands and driven by individual motors. The wheels usually float, as in the straight-line machine. Machines of this type are essentially high production machines. The use of several polishing wheels, coated with different sizes of abrasive from the coarsest to the finest, enables a piece to be finished complete in one passage through the machine. These machines are used largely for finishing flat-iron sole plates, automobile hub caps, and similar work.

**Contour Machines** for polishing or buffing articles of rectangular outline or forms not truly circular, are essentially a rotating spindle which carries the work, combined with a mechanical movement which causes the work to approach or recede from the wheel in conformity with the contour, and which maintains uniform contact of the work and wheel at all times. The mechanical movement may be a cam of appropriate shape or a geared chuck.

The geared chuck (Fig. 19) consists of a chuck, on the back of which is mounted an internal gear, or continuous rack *A*. The pitch line of the rack is parallel to the outline *B* of the surface to be finished. The outside edge *C* of the rack also is parallel to the outline *B*, and bears against a roller *D* which is mounted on the machine frame. A pinion *E* drives the rack. The centers of the polishing or buffing wheel, roller, and pinion, should be in the same straight line. The rack being held always in the same relative position to the wheel by the roller and pinion, rotation of the pinion will cause every point of the outline *B* to come in contact with the wheel.

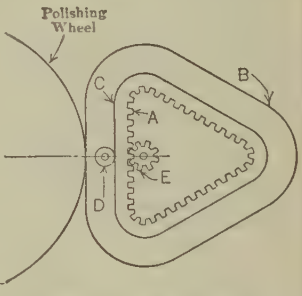

FIG. 19. Geared Chuck

**Special Machines** have been built for many different purposes including the finishing of ice-skate blades, windshield wipers, blank book backs, sewing thimbles, tubing, sheet and strip metal, heads of screws and bolts and various forms of cutlery. Some of these machines employ polishing wheels in pairs, the work passing between the wheels in order to finish two sides at one operation.

**PRINCIPLES FOR POLISHING AND BUFFING MACHINE DESIGN.**—The following principles should be embodied in polishing machines: 1. *Variable Wheel Speed.* Where a machine is to be used with wheels of a variety of diameters, or where the diameter decreases in service, as with a buffing wheel, provision should be made for a variable-speed wheel spindle. Wheel speed then may be maintained constant at the most efficient point. 2. *Variable Work Speed.* Provision should be made to vary the speed at which the work moves past the wheel. The time required for a wheel to do its work varies with different materials, and provision should be made to change the work speed as necessary. Work speeds range from 200 ft. per min. with strip zinc, to 15 ft. per min. with stainless steel. Hardness of material and character of finish desired also influence work speed. 3. *Variable Wheel Pressure.* Excessive pressure of the wheel on the work may damage the wheel and work, change the character of the finish, and increase the cost of polishing or buffing. Hence, all machines should have provision to regulate wheel pressure. 4. *Wheel Oscillation* in an axial direction is desirable to avoid deep scratches and wheel marks. 5. *Vibration* should be eliminated by adequate foundations, sufficient weight in machine bases, shafts of adequate diameter, ample bearings and dynamic balance of rotating parts. Machine vibration will spoil finished surfaces and increase costs. 6. *Work Holding Fixtures* of such design as to properly present work to the wheel, and to facilitate rapid loading and unloading greatly reduce the cost of machine operation.

For many data on the design and operation of polishing and buffing machines, see Robert T. Kent, Fundamentals of Machine Polishing, *Trans.* A.S.M.E., MSP–53–9, 1931.

# BROACHING *

**THE BROACHING PROCESS.**—Broaching is suited for machining holes of any shape, and is an economical method for the duplication of parts in quantity. A large variety of work may be handled without holding fixtures, and intricate shapes are easily held in simple jigs. The accuracy of broaching is comparable to that of milling under ideal conditions.

**BROACH TERMINOLOGY.**—Certain terms have come to apply, through common usage, to various types of broaching tools.

**Keyway Cutter, or Cutterbar** (Fig. 1).—A broach of rectangular section operating in a slotted bushing which adapts it to the bore of the piece in which the keyway is to be cut. The depth of cut may be regulated by a shim in the work bushing slot below the cutterbar.

**Round Broach** (Fig. 2).—A broach for bringing to size a hole which has been drilled, bored or cored round before the broaching operation.

**Multiple Spline Broach** (Fig. 3).—A broach designed to produce simultaneously two or more keyways in one bore. Its common forms are the 6-, 10- and 12-spline broaches used on automobile transmission gears.

**Square Broach** (Fig. 4).—A broach to produce a square hole, starting from a drilled round hole, or a cored square hole.

**Roughing Broach.**—A broach designed to remove a large amount of metal and prepare the hole for the sizing broach, which brings the hole to size and imparts a smooth finish. The roughing broach, not being of such accurate dimensions is cheaper to make and may be re-ground when dull.

**Pull Broach.**—A broach operated by applying power to the shank of the tool and drawing it through the work.

**Push Broach** (Fig. 5).—A broach forced through the work by applying pressure at the finishing end. Presses of various types are used for this work.

**BROACH MATERIAL.**—Broaches are made of carbon steel of 1.00 to 1.10% carbon, high-speed steel, and occasionally of case-hardened machine steel. The latter has a carbon content of about 0.25%. Broaches made from it are case-hardened in a tube packed with charred granulated bone, by heating to 1700° F., cooling slowly, reheating to 1450° F., and then quenching. They are drawn to a temperature of 375° F. Carbon-vanadium steel also is used. It is hardened at from 1350 to 1425° F., and drawn to a temperature of about 460° F.

**MATERIALS THAT MAY BE BROACHED.**—Cast iron, brass, aluminum and steel are readily broached, and many parts made of fiber have been handled satisfactorily.

Soft " stringy " steels often tear out at the edge of the hole. This can be eliminated

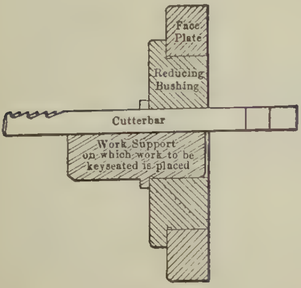

FIG. 1

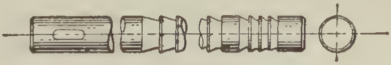

FIG. 2

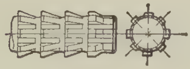

FIG. 3

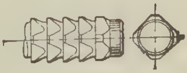

FIG. 4

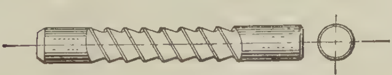

FIG. 5

---

and the finish improved by heat treating to give a scleroscope hardness of from 25 to 30. Harder material causes excessive wear on the broach.

**PREPARING WORK FOR BROACHING.**—The hole in which the broach is to start should be drilled or bored. It is possible to broach from a cored hole, but the sand and scale soon impair the accuracy of the broach. The face of the work that rests against the face-plate of the broaching machine should be finished true with the bore.

**BROACH DESIGN.**—**Pitch of Teeth.**—For best results three teeth usually should be in the work at one time, although this varies with the conditions. A formula which has been published and which may be used for determining approximately the proper tooth pitch for broaches is as follows:

$$P = \sqrt{L} \times 0.35,$$

where $P$ = pitch of tooth, and $L$ = length of work.

**Depth of cut** for each tooth depends largely upon the pull that the smallest section of the broach will stand. In general, the minimum cut should be 0.00075 in. and rarely should it exceed 0.004 in. per tooth. The rise of the successive teeth depends on the material being broached, its hardness and toughness, and the proportions of the broached surfaces. For cast iron or brass, it may be double the rise for steel. Tooth rise usually is greater for the first few teeth on the broach, the rise diminishing toward the finishing end. The last four teeth on the broach or the last 2 in. are made to full cutting size so that the cutting teeth may be sharpened several times without reducing the size of the broached hole.

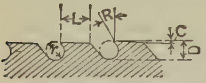

FIG. 6

Other tooth dimensions are as follows (see Fig. 6): $D$, the total depth of tooth depends on the diameter of the broach. It must be calculated for every tool, to provide as much chip room as possible without weakening the tool beyond a reasonable factor of safety; $r$, the radius at the bottom of the tooth should be slightly more than half the total depth of the tooth; $P$ should be slightly more than $^1/_2$ $D$; $L$ = $^1/_{16}$ in. to $^1/_8$ in.; $C$ = 1 $^1/_2$ deg. to 3 deg.; $R$ = 8 deg. to 10 deg.

Push broaches generally are made from 6 to 15 in. long, depending on the character of the work. Several may set in sequence in order to produce the desired finish and accuracy. Pull broaches may be made of any length necessary, and usually are designed to finish the hole at one pass of the broach.

**Chip Breaking.**—In designing round and square broaches, and other types having wide cutting surfaces, chip breakers must be provided. On round broaches a staggered nick should be used. In broaches of small diameter a large number of nicks will be required in each tooth.

**Information Necessary for Design of Broach.**—1. Kind of material broach is to cut, which limits the cut per tooth and the clearance angle at top of tooth. Rake and clearance angles should be identical with those of a lathe tool cutting the same metal. 2. Length of work, *i.e.*, length of surface actually to be broached, which determines the pitch of teeth. This dimension represents $L$ in the formula previously given. 3. Method of preparing the work for broaching, which determines the shank diameter of the broach. If the hole is cored, the first cutting teeth should be made very strong and given sufficient cut to get beneath the scale. Unless two or more broaches are to be used it is not advisable to start the broach in a cored hole as the hard wear on the tool quickly impairs the accuracy. 4. Tolerances. The required limits of the hole to be broached, when finished, should be carefully considered. It is always best to make the broach to the high limit so as to allow maximum wear before the broach is worn undersize. Where work will permit, liberal tolerances should be allowed in the broach dimensions, as this will make the tool less expensive.

**BROACH SPEEDS AND FEEDS.**—Cutting speeds on hydraulic broaching machines range from 10 to 42 ft. per min. Return speeds are from two to four times greater.

**TESTING OF BROACH.**—The broach should be tested in the material in which it is to be used before starting work on a production basis. If there is a tendency to "drift" or cut oversize on any side, the side from which the broach drifts should be examined for dull teeth, and these sharpened with an oil stone.

**CAPACITY OF BROACH.**—A broach should be used only in work for which it was designed. If the piece to be broached is longer than that for which the broach was designed, there will not be sufficient chip clearance. The teeth will fill with chips and roughen the surface of the work. If the strain becomes too great, the broach will break. If the work is much shorter than the intended capacity of the broach, there will not be enough teeth in the work to prevent crawling and cutting oversize. The broach then should be changed or redesigned in accordance with the formula given above.

**LUBRICATION.**—The cutting lubricant is important in broaching operations. There is a wide difference of opinion as to the best lubricant for various metals. Those mentioned below have been used successfully.

**For Cast Iron.**—Soda and water will improve the finish of broached cast iron, will wash chips from the broach teeth, and prevent clogging.

**For Steel.**—A soluble oil made as follows is popular and inexpensive: 2 1/4 lb. soda ash, 3 gal. mineral lard oil, 50 gal. water. Mix the soda and lard oil together in 10 gal. of water, then add 40 gal. of water. Kerosene is frequently added to this mixture if the steel is very tough.

**For Aluminum.**—In broaching aluminum, turpentine or gasoline are satisfactory.

The chief use of the lubricant is to cool the broach teeth and wash out chips. The pump on the broaching machine or press should deliver a sufficient quantity of lubricant to flood the work thoroughly.

Square broaches should be operated with one corner uppermost. The cutting lubricant then flows down and around both sides and does not spatter off, as it would with the flat surface on top. Spline broaches should be so slotted that the channel between two of the splines will be at the top and conduct the lubricant into the hole with the broach.

**Removing Unfinished Work from Broach.**—Should work become stuck on the broach during the cut, by the breaking of broach teeth or crowding of chips in the teeth, further damage to the broach may be avoided by placing it in a lathe and turning the piece away. If the broach has no centers, or it is more convenient, the piece may be sawed through on a milling machine or with a hack saw.

**Care of Broaches.**—Clean the broaches after using and store them on racks or shelves where teeth are in no danger of striking metal objects. Many broaches are ruined by dropping on the floor or striking hard objects which chip the teeth.

**SURFACE BROACHING** is a process of machining the surface of work by means of a broach of appropriate contour, and producing a finished surface from the rough piece in a single operation. The finished surface may be plane, curved or a combination of the two. Surface broaching is essentially a high-production operation, and since its inception about 1932 has replaced many milling operations, especially in the automotive industry. It also is used to replace surface grinding, and to rough and finish gears.

High-speed steel generally is used for surface broaches, although for certain classes of work, broaches with teeth tipped with cemented carbide have been used. Surface broaches generally are made in sections, from 6 to 14 in. long. The sections are assembled in a holder which is mounted on the ram of the broaching machine. Details of tooth spacing, chip thickness, clearances, etc., must be determined for each job. Usually some experimenting is necessary to ascertain the best form of the broach for production work.

Surface broaching has been used to machine the bearing surface and parting faces of automobile engine connecting rods, automobile steering knuckle faces, slots in speed reducing rings, shock absorber arms, certain parts of automobile engine cylinder blocks, notches in Stillson wrench and plier faces, slots in castle nuts, wrench openings, and many other similar operations. The speed of surface broaching is from 15 to 25 times as fast as for milling similar work. Joseph Geschelin, Current Practice in Surface Broaching (*Trans.* A.S.M.E., MSP—56–1, 1934) gives data of a number of surface broaching jobs. See Table 1.

**Table 1.—Surface Broaching Operations**

| Work | Operation | Material | Broach | | | | Cutting Compound |
|---|---|---|---|---|---|---|---|
| | | | Length, in. | Speed, ft. per min. | 1000 Pieces per Grind | Life, 1000 Pieces | |

Millard Romaine (*Trans.* A.S.M.E., vol. 57, 1935, p. 258) discusses the limitations of surface broaching. He shows it to be best adapted to jobs where the stock removal is comparatively small (say $^1/_4$ in. maximum) and where this stock is held within fairly close limits. A large quantity of stock to be removed necessitates an excessively long broach, with a resultant increase in the time per piece. Otherwise, excessive pressure is put on the first tooth, causing increased wear and increasing the hazard of breakage. Surface broaching has the advantage of high production and low labor cost, but has the disadvantage of high tool cost as compared with milling. At the present stage of development (1937) it is limited to the high-production industries.

**SURFACE BROACHING MACHINES** are made both horizontal and vertical, single and duplex, and for hydraulic and mechanical operation. One type of vertical machine has two broach holder slides that counterbalance each other, one rising while the other is descending on the working stroke. Each slide carries a rack meshing with a helical pinion driven by a motor. Other types use hydraulic cylinders to actuate the slides. In some machines, the hydraulic plunger pushes the broach across the work and in others it pulls it. In the duplex machines, work is clamped in fixtures mounted on a table that swings the work into the path of the descending broach. The other fixture is simultaneously swung away from the ascending broach for unloading and loading.

The following are data of vertical duplex surface broaching machines as built by the Cincinnati Milling Machine Co.:

| | | | | | | |
|---|---|---|---|---|---|---|
| Max. stroke, in. . . . . . . . . | 36 | 48 | 42 | 54 | 54 | 66 |

**Manufacturers.**—Surface broaching machines are built by American Broach and Machine Co., Ann Arbor, Mich.; Cincinnati Milling Machine Co., Cincinnati; Foote-Burt Co., Cleveland; LaPointe Machine Tool Co., Hudson, Mass.

# METAL SAWING

The generally-used methods of sawing metal are: 1. Hand hack saws, for occasional jobs at the bench, or on assembly work on the floor or in the field; 2. Power hack saws, for production work on all types of material and on light and heavy sections; 3. Band saws for production work on light and medium sections, and for sawing irregular contours; 4. Circular cut-off saws for very heavy sections; 5. Friction discs, for rails, structural sections, billets, bars, slabs, etc., either hot or cold.

## 1. HACK SAWS

**HACK SAW BLADES** generally are of high-speed steel, although carbon steel and semi-high-speed steel also are used for some purposes. Teeth are of various forms, arranged to cut only in one direction. Teeth without rake are the most common. Teeth with negative rake are used for thin sections, but require greater cutting pressure than straight teeth. Table 1 gives data on standard high-speed steel blades. The following are the fields of the several classes of teeth: *Regular*, soft steel, cast iron, bronze; *medium*, annealed high-carbon steel, high-speed steel; *fine*, solid brass, iron pipe, heavy tubing; *tubing*, thin tubing, sheet metals. Pitch of teeth also should be chosen with reference to

the size of the section being cut. For wide heavy sections, coarse pitch teeth should be used to give ample chip clearance. For thin sections the pitch should be chosen so that two or more teeth are in contact with the work. Otherwise, the teeth will straddle the work and strip the saw.

O. W. Boston and C. E. Kraus, *Trans.* A.S.M.E., RP–56–5, 1934, describe tests to determine the performance of hack saws when operated with different cutting fluids on various metals. Of the eleven fluids tested, a sulphurized mineral oil with asphaltic base containing 4.38% sulphur, and a viscosity of 105 seconds at 100° F., was found to be the best, giving the least sawing time and the least wear on the blade.

**HACK SAW MACHINES,** or power hack saws, range in capacity from stock 4 in. square up to stock 13 × 16 in. One type, built with a gap-frame, can cut stock 16 × 26 in. by turning the work over when half sawed through. Stroke of saw is 4 in. in the smaller machines to 6 in. in the larger ones. Some machines feed by gravity, the saw frame being provided with weights that can be shifted to give greater or less pressure on the saw as required. Other machines have a positive feed which ranges from 0.001 to 0.025 in. per stroke, depending on the class of material cut. When hard spots are encountered, the feed automatically is stopped or shortened to decrease the pressure on the saw until the hard spot has been cut through. All machines lift the saw clear of the work on the return stroke. Hack saw machines are both belt-and motor-driven. Motors range from $^1/_4$ Hp. for a 4 × 4 in. machine to 2 Hp. in the largest size. High duty machines have three speeds. The Racine Tool and Machine Co. recommends the following speeds, in strokes per min.: For cold-rolled or machine steel, brass, soft metals, 135; alloy steel, annealed tool-steel, cast iron, 90; high-speed steel, unannealed tool-steel, non-corrosive steel, 60. Cast iron should be sawed dry. Other materials should be sawed with a cutting compound of water to which sufficient soluble oil has been added to whiten it. The principal function of the fluid is to cool the saw.

## 2. BAND SAWS

Metal sawing band saws are similar in appearance to band saws for woodworking. They range in capacity from the lightest sections up to work 12 in. thick, and are made in sizes from light bench-type machines to heavy production equipment. They are widely used in non-ferrous foundries for cutting of gates, sprues and risers. Band saws are built with one or more speeds to adapt them to a variety of metals. Speeds used are as follows, in feet per minute: Aluminum, 1000–2500; brass (sheets and tubes), 750–1500; cast iron, 100–150; malleable iron, 150–200; steel, 100–200; steel (high-speed) 90–120. Hand or power feed may be used. In some machines the work is fed along the table, and in others, the work is stationary, and the column and saw fed into it. Band saws are especially adapted to light thin sections, which would easily be bent out of shape by the heavier pressure of the hack saw, and to saw pieces of shapes that are inaccessible to the hack saw or circular saw.

## 3. CIRCULAR CUT-OFF SAWS

Circular cut-off saws fall into two general classes: 1. Saws with teeth whose action is similar to that of a milling cutter; 2. Friction or abrasive discs.

**METAL CUTTING SAWS** are made with teeth cut in the periphery of the disc or with inserted teeth. Saws up to 8 in. diameter generally are termed metal-slitting saws. From 9 in. diameter to 60 in., or larger, they are called cold saws.

**Metal Slitting Saws** are made with a variety of forms of teeth for sawing different materials. For steel, the teeth either are plain or have side clearance. The latter have a rake of about 10 deg. For heavy work in steel, alternate teeth have side clearance on opposite sides. For cast iron the teeth are more widely spaced than for steel, and have side clearance, and a rake of 3 to 4 deg. For non-ferrous metals, widely spaced teeth with side clearance and a rake of about 13 deg. are used. The body of the saw should be thinner than at the periphery, or the teeth should be offset to provide ample kerf to clear the saw.

Speeds and feeds with metal slitting saws vary with the class of material cut. For cast iron, speed ranges from 70 to 90 ft. per min. and feed from 3 to 6 in. per min. For ordinary steel, speeds range from 110 to 125 ft. per min., and feeds from 5 to 8 in. per min. Corresponding figures for alloy steel are 50 to 60 ft. speed, and $^1/_2$ to 2 in. feed. Brass may be cut at speeds up to 250 ft. per min., with feeds of 10 or 12 in. per min. Speeds for copper range from 150 to 300 ft. per min., and for aluminum 500 to 600 ft. per min. speed, with feeds of 10 to 20 in. per min. for both metals.

**Inserted Tooth Saws** comprise a disc, in the periphery of which notches are cut, into which cutting teeth of high-speed steel, or of steel tipped with cemented carbide are inserted. The method of holding the inserted teeth forms the principal point of difference

Table 2.—Cutting Speed and Rake Angle of Inserted Tooth Saws for Various Metals

| Material | Cutting Speed, ft. per min. | Tooth Rake, deg. | Material | Cutting Speed, ft. per min. | Tooth Rake, deg. |
|---|---|---|---|---|---|
| Aluminum | 1200 | 25–30 | Steel, 42–64,000 T. S.* | 80–90 | 15 |

* Tensile strength, lb. per sq. in.

in saws as built by various manufacturers. Rake angle varies with the material being cut as shown in Table 2, adapted from O. W. Boston, Engineering Shop Practice (John Wiley & Sons). Clearance angles range from 5 to 12 deg.

Feeds with inserted tooth saws range about as follows, the figures being inches per min.: Aluminum, 90; brass, 80; cast iron, 5; copper, 60; steel 2–10.

**COLD SAW CUT-OFF MACHINES** are built with a range of speeds and feeds. They usually are individually motor-driven. Work-holding fixtures may be adapted to present work to the saw at various angles, to grip work of irregular shape, as structural sections, and to take either single pieces or a large number of pieces which are sawed at a single setting.

**FRICTION DISCS** are relatively thin discs of alloy steel which are rotated at peripheral speeds of from 20,000 to 25,000 ft. per min. The intense heat, generated by the friction of the saw against the work, fuses the metal of the latter. The disc, which is water-cooled, thus makes a thin slit in the work similar to a saw cut. Frequently, teeth of V or square shape are cut in the periphery of the disc. These teeth do not have any cutting effect, but serve to increase the friction and thus accelerate the generation of heat. When worn down they are re-cut. Friction discs are widely used for cutting off structural sections and bars. Their action is extremely rapid, cutting off 8-in. I-beams in from 5 to 15 seconds, and 40-in. beams in about $1\frac{1}{2}$ minutes. Friction discs are mounted in motor-driven machines, which often rotate the work as well as the disc.

For data on design and operation of friction saws, for sawing hot structural sections, see A. B. Pearson, Design and Construction of Hot Saws for Cutting Heavy Sections, *Trans.* A.S.M.E., IS–52–10, 1930.

**ABRASIVE CUT-OFF DISCS** are very thin abrasive wheels which are used in cut-off machines mainly for cutting off smaller sections and bars, of very hard materials and the non-ferrous metals.

## MACHINE TOOL MOTOR DRIVES

**SIZES OF MOTORS FOR MACHINE TOOLS.**—The size of motor applied to a machine tool driven by individual motor usually is determined by the experience of the manufacturer, rather than by any formula. The same lathe, for instance, will be fitted with a larger motor if it is required to take heavy roughing cuts continuously in tough steel, than if it is to have a more general run of lighter work in cast iron. Even if it does, under the latter conditions of service, occasionally receive a job up to the limit of its capacity, the motor will be able to stand the temporary overload, whereas a continuous overload soon would ruin it. The conditions under which the machine will operate should, therefore, be stated when it or the motor to drive it is purchased. Tables 1–19 give sizes of motors for machine tools as recommended by the Westinghouse Elect. & Mfg. Co. The sizes given embody average practice. The type of motor to be used varies with the conditions of service, and the type suitable for the different classes of machinery are indicated by the following symbols (see also p. 25–50):

*A.* Adjustable-speed, shunt-wound, direct-current motor; used where a number of speeds are essential.

*B.* Constant-speed, shunt-wound, direct-current motor; used when the desired speeds are obtainable mechanically by a cone pulley or gear box, or where only one speed is required.

*C*. Squirrel-cage induction motor; used where direct-current is not available. A cone pulley or gear box is necessary if more than one speed is desired.

*D*. Constant-speed, compound-wound, direct-current motor, used when different speeds are obtainable by means of a cone pulley or gear box, or where but one speed is necessary.

*E*. Wound secondary or squirrel-cage induction motor with about 10% slip; used where direct-current is not available, or where one speed is required.

*F*. Adjustable-speed, compound-wound, direct-current motor; used where a number of speeds are necessary.

*G*. Standard bending roll motor.

*H*. Standard machine tool traverse motor.

**GROUP DRIVES.**—While the tendency is to drive machine tools, especially the larger ones, with individual motors, there are nevertheless many conditions under which group drive will be more economical. Group drive may take various forms. For example, a series of line-shafts, each driven by a motor, with countershafts for the individual machines, is one form. Another form is a series of motor-driven short jack-shafts, driving directly a compact group of similar machines, the control and speed variation mechanism being built into the individual machines. The total motor horsepower required with group drive may range from 1/3 to 3/4 of the sum of the total power required by the individual machines, since, under the conditions under which group drive should be used, only part of the machines will be operating at any one time. The higher the load factor, the smaller are the advantages of group drive.

No definite rules can be laid down either for the arrangement of group drives or the motor capacity necessary. Each installation must be designed to conform to the conditions under which it is to operate. In general, however, the motor requirements will be the sum of the total machine horsepower multiplied by the average load factor, plus the friction loss of the line- and countershaft bearings. Motor capacity somewhat in excess of the figure so found is advisable to take care of short peaks when more machines than the average may be in operation.

The following figures show the average power utilized, in percentage of actual machine power, in group drives on various classes of work. These figures, which are given for example only, should not be used in design, as they will vary in every case with load factor, character of material cut, and with variation in machine speed, depth of cut and rate of feed.

Engine lathes, 16-in., 10–20%; automatic lathes, 36%; vertical lathes, 74%; plain milling machines, 50%; horizontal milling machines, 4-head, 35%; turret-lathes, 55%; drill presses, 24-in., 19%; multiple-spindle drills, 30%; horizontal boring mills, 18.5%; cylindrical grinders, 23%.

# MEASUREMENTS

Measurements in the machine shop may be roughly classified as non-precision, semi-precision and precision measurements. Non-precision measurements may be defined as those in which the permissible limit of error is 0.01 in. Semi-precision measurements may be defined as those in which the permissible limit of error is 0.001 in. Precision measurements are those in which the permissible limit of error is less than 0.001 in. High-precision measurements can be made within less than 0.0001 in.

## 1. NON-PRECISION MEASUREMENTS

**THE FOOT RULE** or machinist's scale ordinarily cannot be used for direct measurement with an accuracy closer than $^1/_{64}$ in., although highly expert machinists can set calipers by means of the machinist's scale to within 0.01 in.

**CALIPERS,** considered as non-precision measuring devices, may be of two types: *a.* Those that transfer a dimension from a scale or gage block to the work, or *vice versa.* *b.* Those in which the measuring scale is incorporated in the caliper itself, as shown in Fig. 1. When a vernier is added to the caliper of Fig. 1, it becomes a semi-precision measuring instrument, as the instrument then can be read to 0.001 in. The micrometer, although actually a semi-precision instrument, may be used to advantage for non-precision measurements, because of its accuracy and ease of setting to a given dimension. If a vernier is added to the micrometer it becomes a precision instrument.

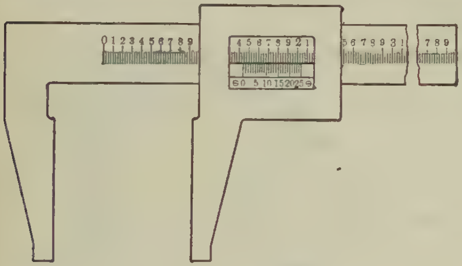

FIG. 1. Vernier Caliper

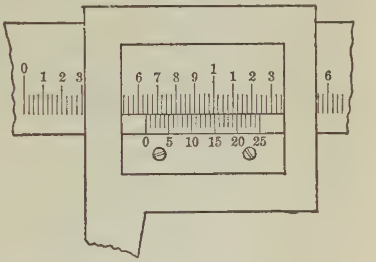

FIG. 2. Vernier

## 2. SEMI-PRECISION MEASUREMENTS

**THE VERNIER CALIPER** is shown in Fig. 1. Each main division of 0.1 in. on the scale is divided into four subdivisions. Hence, each space on the scale equals $^1/_{40}$ in. If a distance of 0.6 in. on the vernier, *i.e.*, 24 spaces on the scale, be divided into 25 spaces, the vernier will read to 0.001 in., since $^1/_{25} \times {}^1/_{40} = {}^1/_{1000}$. The vernier is read by noting the number of the division on the vernier scale that exactly coincides with a division on the main scale. This number on the vernier is the distance in thousandths of an inch that is to be added to the reading on the main scale corresponding to the number of divisions over which the zero of the vernier has moved.

EXAMPLE.—In Fig. 2, the reading on the main scale is 0.625+ in. (Each small division on the scale = 0.025 in.) The division .019 on the vernier exactly coincides with a division on the main scale. The reading of caliper then is $0.625 + 0.019 = 0.644$ in.

**THE MICROMETER** ordinarily is read to the nearest 0.001 in. The main divisions of the scale on the frame are 0.1 in., each division being subdivided into 4 equal divisions. Each space on the stem then equals $^1/_{40}$ in. (0.025 in.), which is the pitch of the micrometer screw. The circumference of the thimble is divided into 25 equal spaces. Each space on the thimble represents $^1/_{25} \times {}^1/_{40} = 0.001$ in. By the addition of a vernier scale to the stem, the micrometer can be read to 0.0001 in. The reading on the frame, plus the reading on the thimble, plus the reading on the vernier is the total distance that the end of the stem has been moved out from the anvil.

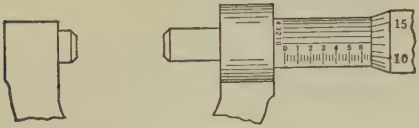

FIG. 3. Vernier Micrometer

EXAMPLE.—The thimble of the micrometer, Fig. 3, has uncovered 6 main divisions and 3 subdivisions on the frame. The scale on the thimble shows that it has been turned through 12+ divisions past the zero line on the frame. The third line on the vernier scale exactly coincides with a line on the scale on the thimble. The reading of the micrometer then is:

| | | |
|---|---|---|
| Scale on frame | 0.6 + (3 × 0.025) = | 0.675 |
| Scale on thimble | 12 × 0.001 = | .012 |
| Scale on vernier | 0.0003 = | .0003 |
| Micrometer reading | | 0.6873 |

**DIAL INDICATORS,** Fig. 4, may be used both for semi-precision and precision measurements as they are made to measure to 0.001 in. or 0.0001 in. By splitting the graduations on the dial, readings can be taken to half of the foregoing amounts. The indicator consists essentially of a movable spindle on which is cut a rack, meshing with a gear train which actuates the pointer. Movement of the spindle causes rotation of the pointer, the amount of the spindle movement being indicated by the graduations on the dial. A hair spring within the instrument returns the pointer and spindle to their initial positions when the pressure on the spindle end is removed. The dial can be rotated to bring zero opposite any position of the pointer.

Dial indicators are used in many different ways. One of the commonest uses is that of an inspection gage, as shown in Fig. 5. The instrument is set by means of a gage block or other means to the desired dimension, with sufficient pressure on the spindle to rotate the pointer through one turn. The dial then is set to zero opposite the end of the pointer. The work to be inspected is placed under the spindle and the deviation plus or minus from the standard dimension can be read on the dial. Other uses of the dial indicator are measuring the depth of holes, determining out-of-roundness of circular pieces, the setting of work parallel with a given plane, etc. When used as a depth gage, the indicator is mounted on a base through which the spindle may be projected downward by a push button until it strikes the bottom of the hole. For determining out-of-roundness, the work may be centered in a lathe. The indicator is placed in the tool post, with the spindle bearing on the work. Dial indicators are made in a variety of forms for special purposes. For details of the various forms, see catalog of L. S. Starrett Co., Athol, Mass.

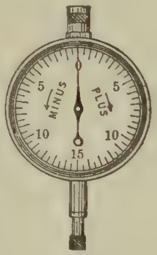

FIG. 4. Dial Indicator

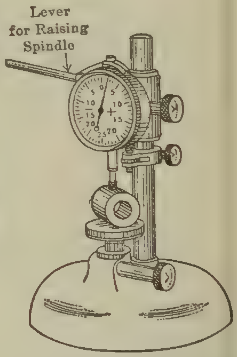

FIG. 5. Dial Indicator Used as Inspection Gage

## 3. PRECISION MEASUREMENTS

**MEASURING MACHINE.**—The standard measuring machine as built by the Pratt & Whitney Co. is a machine for originating or duplicating measurements within 0.000 01 in. It is used for checking of master gages which in turn are used to check the service gages used in manufacturing operations. The basis of the machine is a measuring bar at the rear of the machine in which are inserted at 1-in. intervals hardened steel plugs marked with a microscopic line. These graduations on the measuring bar are calibrated at the U. S. Bureau of Standards.

The measuring head consists of an anvil which is advanced by a measuring screw, the pitch of which is $^1/_{25}$ in. An index wheel on the screw is graduated to read directly to 0.0001 in., and by means of a vernier can be read to 0.000 01 in. The tailstock of the machine is set with the face of its anvil opposite the zero point on the measuring bar. The head stock, or measuring head, is set to the next greater inch on the measuring bar than the length of the piece to be measured; the fractions of the inch are determined by the measuring head. A microscope is used to determine the coincidence of the zero lines on the heads and the inch marks on the measuring bar. The work to be measured is supported on elevated ways in the plane of the anvil, with one end in contact with the tailstock anvil. The measuring head anvil then is carefully advanced by means of the screw until it bears against the opposite end of the piece to be measured. Provision is made in the machine that the pressure of the anvil on the work always will be duplicated at each measurement, this pressure ranging from 8 oz. to 3 lb., depending on the character of the work being measured.

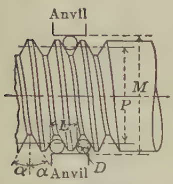

Fig. 6. Thread Measurement by Three-wire Method

The measuring machine is widely used for the measuring of pitch diameters of thread gages by the 3-wire method as shown in Fig. 6. The *wires* are steel rolls of uniform hardness. They must be uniformly round and hard, and must be straight and round within 0.000 02 in., and of the same diameter within 0.000 02 in. Furthermore, they must be the theoretically correct size within 0.000 02 in. The recommended sizes of wire for checking 60-deg. threads are given in Table 1. The pitch diameter of a thread whose sides are symmetrical about a line through the vertex perpendicular to the axis of the thread is

$$P = M + (\text{cotan}\ \alpha/2\ n) - D\ (1 + \text{cosec}\ \alpha) \quad . \ . \ . \ . \ . \ . \ . \quad [1]$$

For a 60-deg. thread with a helix angle smaller than 6 deg., equation [1] becomes

$$P = M + (0.86603/n) - 3\ D \quad . \ . \ . \ . \ . \ . \ . \quad [2]$$

For a helix of 6 deg. or more, the equation becomes

$$P = M + (\text{cotan}\ \alpha/2\ n) - D\ \{1 + \text{cosec}\ \alpha + (T^2/2)\cos\alpha\ \cot\alpha\} \quad . \ . \quad [3]$$

In these equations $P$ = pitch diameter, $M$ = measurement over the wires, $\alpha$ = 1/2 included angle of thread, $n$ = threads per inch, $D$ = diameter of wires, $T$ = tangent of helix angle = $L/\pi P$, where $L$ = lead of thread.

**Table 1.—Recommended Wire Sizes for Measuring 60-deg. Threads**

All dimensions in inches

| Threads per in. | Wire Size | Threads per in. | Wire Size | Threads per in. | Wire Size | Threads per in. | Wire Size | Threads per in. | Wire Size | Threads per in. | Wire Size |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 80 | 0.00722 | 44 | 0.01312 | 27 | 0.02138 | 14 | 0.04124 | 10 | 0.05773 | 5 | 0.11547 |
| 72 | .00802 | 40 | .01443 | 24 | .02406 | 13 | .04441 | 9 | .06415 | 4 1/2 | .12830 |
| 64 | .00902 | 36 | .01604 | 20 | .02887 | 12 | .04811 | 8 | .07217 | 4 | .14434 |
| 56 | .01031 | 32 | .01804 | 18 | .03208 | 11 1/2 | .05020 | 7 | .08248 | 3 1/2 | .16496 |
| 48 | .01203 | 28 | .02062 | 16 | .03608 | 11 | .05249 | 6 | .09623 | 3 | .19245 |

**THE ELECTROLIMIT GAGE** is a comparator that will measure under shop or production conditions to 0.000 005 in. The principle of the gage is shown in Fig. 7. The spindle $S$ with which the work to be measured is brought into contact, is continuously in contact with the armature $A$ that floats midway between the electromagnet coils $M_1$ $M_2$. The coils are so adjusted by screws $W$ that the current in them is balanced when the armature $A$ is central between the coils. A movement of spindle $S$, as produced by contact of work with it, changes the position of $A$ with respect to $M_1$ and $M_2$. The magnetic fields then are unbalanced, producing a corresponding unbalance in the current in the coils. The amount of unbalance and, therefore, the movement of spindle $S$ is shown on a microammeter, the scale of which is graduated to read in decimals of an inch suitable to the character of the work being measured. The armature $A$ is carried by a flat spring pivot $P$, at one end, and always is returned to a central position by suitable springs and stops.

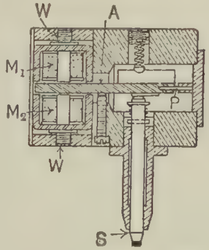

Fig. 7. Principle of Electrolimit Gage

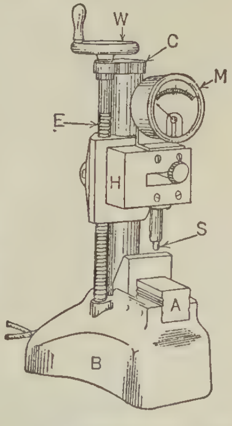

Fig. 8. Electrolimit Gage Used as a Comparator

The gage can be arranged in many different ways to adapt it to the particular type of work on which it is to be used. Several heads (Fig. 7) may be arranged in combination to measure two or more dimensions simultaneously, or to determine squareness or parallelism of a piece at the same time that a dimension is determined. Fig. 8 shows the device arranged as a simple comparator. The base $B$ supports the column $C$, which carries the gaging head $H$. The position on the column of the gaging head may be varied by the elevating screw $E$ and hand wheel $W$. The a handle. Double plug gages, Fig. 14, with a knurled handle between them are used as limit gages, the two plugs being lapped to the minimum and maximum diameters representing the prescribed limits. Plug gages should be made single-ended. If they are to be double-end limit gages, they should be made as two single-end gages with a hole in the gage into which the handle is fitted. The handle is shouldered and held by a nut. In screw gages, it also is keyed. The " no go " gage should be made shorter than the " go " gage in order to distinguish it.

Hilding Tornebohm (*Mech. Engg.*, July, 1936, p. 411) describes a combined "go" and "no go" gage that is used in Sweden. It comprises a spherical body *A*, Fig. 15, of the same diameter as the minimum permissible dimension of the hole. Near the outer edge of the body is a spherical projection *B*. The distance from the surface *B* to the diametrically opposite point on *A* is equal to the maximum permissible dimension of the hole. The gage is used by inserting it in the hole with the axis of the handle parallel to the axis of the hole. If it will enter, the hole is larger than the minimum limit. The handle then is tilted to the position *C*, moving projection *B* to position *D*, in contact with the side of the hole. If the tilting movement is impeded the diameter of the hole is less than the maximum limit. If it is not impeded the hole is too large. By turning the gage in the hole to several different positions, and tilting it as described above, the hole may be checked for roundness. Any ellipticity of the hole, within the tolerance built into the gage, *i.e.*, the distance that *B* projects above the surface of the spherical body *A*, is immediately detected. Such a check for ellipticity is not possible with the conventional plug gage.

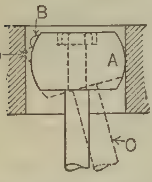

Fig. 15. Combined "Go" and "No Go" Spherical Plug Gage

Ring gages similarly may be bored and lapped to maximum and minimum diameters and used as " go " and " no go " gages. Ring gages should be knurled on the outside, and should be heavily chamfered on the " go " end to distinguish it from the " no go " end.

**Screw Plug and Ring Gages** are used to determine the correctness of screw threads. Both " no go " plug and ring gages are made to check pitch diameter only. The crest of the thread is removed down to the specified dimension of the major diameter of the " go " gage. That portion of the thread at the root of the standard form also is removed. The minimum length of thread parallel to the axis of the gage is 1.5 × basic diameter. The end threads on screw gages, both plug and ring should be flattened, not chamfered, to avoid forming a feather edge. Ring gages should be made adjustable. Plug gages for inspection service should be provided with dirt grooves extending into the gage a depth equal to one to four threads. For tolerances and limits on standard screw threads, see pp. 9–06 to 9–13. For the three-wire method of checking pitch diameter of thread gages, see p. 21–109.

**CONTOUR GAGES** are used to determine the correctness of contour of a piece. Fig. 16 shows a typical contour gage, which not only gages the contour, but determines whether or not a hole in the work is correctly located. The pin *a* is fitted into the hole in the work, which also should fit the contour in the gage recess. If limits are to be maintained, contour gages also may be made " go " and " no go."

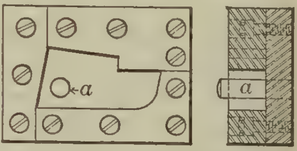

Fig. 16. Contour Gage

**STEEL FOR GAGES.**—A satisfactory steel for snap gages is a machine steel containing 0.20% C, 0.90 to 1.10% Mn, with S and P not over 0.05%. Silicon should not be present, as it tends to warp the gage in hardening. Carbon may be as low as 0.15% and as high as 0.25%. For plug and ring gages carbon may be as high as 0.50%. Gages made of these steels are pack hardened and ground. High-carbon steel, with 0.90% C, 0.30% Mn, S and P not over 0.025, and 0.15% Si, often is used for gages. When made of this steel, they can be hardened more rapidly than the machine steel gages. Alloy steels also are used for gages.

**PRECISION BLOCK GAGES** consist of a series of flats, either round or square, of hardened steel, with parallel opposite faces, lapped flat to within one or two millionths of an inch of the dimensioned size. These blocks can be wrung together to form a single gage of any desired length, with a cumulative error so small that it can be determined only by means of extremely accurate measuring apparatus. Prior to 1920, all precision blocks were imported into the U.S., but since then the Hoke blocks, made by the Pratt & Whitney Co., have had wide use. These blocks are approximately 0.95 in. square, with a hole in the center. They are made in various thicknesses, and arranged in sets. By combination of various sets and individual blocks any dimension up to 20 in. or more, varying by increments of 0.000 05 in. may be obtained. Precision blocks frequently are used as the master gage for checking reference gages.

## 5. SURFACE QUALITY MEASUREMENT

**MEASUREMENT OF SURFACE QUALITIES.**—Improvements in manufacturing methods have enabled the production of finer surfaces, *i.e.*, surfaces which approach more closely a true plane or a true cylinder. Since about 1930, methods of measuring the quality of a surface have been in process of development, and a committee of the A.S.A., sponsored by the A.S.M.E. is (1937) establishing standards for surface qualities and methods of determining them.

The character of surface varies with the method of producing it. Thus, there is a distinct difference between a turned and a milled surface, and other differences between machined and ground surfaces, and still other differences between ground, lapped and honed surfaces. In general, all surfaces consist of a series of more or less microscopic peaks and valleys. The variation in the character of surface depends on the spacing and the heights and depths of the peaks and valleys, and also on their degree of regularity or irregularity in cross-section. Fig. 17 shows characteristics of several different surfaces.

**METHODS OF MEASURING SURFACE QUALITY.**—Several methods have been devised for determination of surface quality: 1. Optical methods which include microscopic or photomicroscopic examination of specially prepared profile sections, usually copper plated before cutting; the projection microscope which throws on a screen an enlarged image of the surface, magnified from 50 to 100 diameters, also has been used. 2. Tracing the surface with a phonograph pick-up and determining the resultant voltage, or amplifying the voltage and applying it to a loud-speaker, thereby permitting a comparison of the sound produced by different surfaces. 3. Tracing the profile by means of a profilograph, which moves a sharp point over the surface. The movements of the point are enlarged by optical methods and recorded photographically. Of the three methods, the last is the only one that has been reduced to commercial use (1937). In the profilograph record the horizontal distances are compressed to about $^1/_{50}$ of their original length by gearing down the photographic drum. This causes all irregularities to appear about 50 times as sharp as they actually are. However, since initially they are relatively dull, it still is possible to distinguish individual irregularities. Fig. 17 shows typical profilograph records. For a detailed description of the profilograph, see *Auto. Ind.*, Aug. 19, 1933, p. 204.

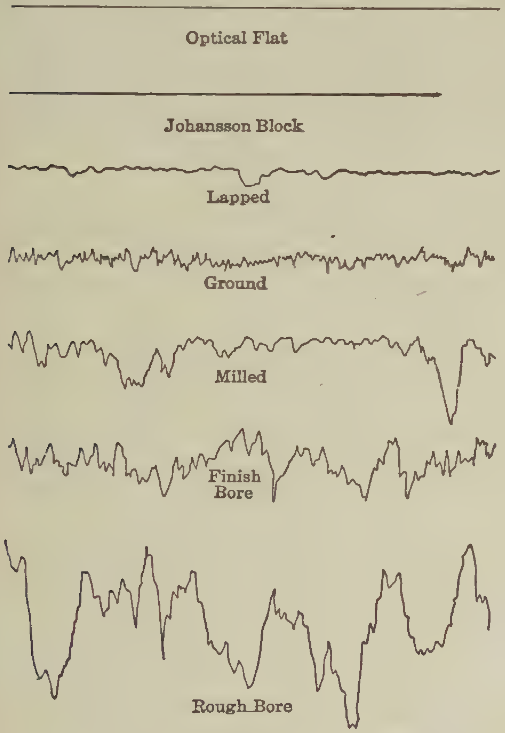

FIG. 17. Characteristics of Various Surfaces

The profilograph is essentially a laboratory instrument. Its development to an instrument for use in the shop in checking the quality of surface in production work is described in *Mech. Engg.*, March 1938, p. 205. The production instrument is known as a profilometer. The tracer point is a sharp diamond held in contact with the work by delicate spring tension. The springs are arranged so that the point is free to move only in a direction perpendicular to the surface being measured. A small coil located in the field of a permanent magnet is mounted integral with the tracer support. Movements of the tracer effect changes in the voltage in the coil which are proportional to the velocity of movement of the tracer point. The voltages are amplified and caused to produce displacements of the spot of a cathode-ray oscillograph, which displacement can be made proportional to the displacements of the tracer points, and magnified vertically to any desired degree. Magnification in a horizontal direction is obtained by photographing the displacements of the oscillograph spot on a film moving at right angles to them. The degree of horizontal magnification is determined by the speed of the film.

Among the characteristics of the profilometer are: Sensitivity sufficient to measure the smoothest metal surfaces, and sufficient ruggedness to measure surfaces 1000 times as rough without change of set up; available magnification far greater than is possible with microscopic equipment; speed of operation about 1000 times as fast as with previous instruments; a continuous running average of height of surface irregularities can be taken automatically and rapidly; presence of individual scratches and other unusual irregularities is indicated; cutting of small specimens from large pieces is unnecessary and measurements can be made directly on practically any surface, and on curved and eccentric pieces without these characteristics affecting either the reading or the record. No damage is done to the specimen and the tracer point lasts indefinitely.

Information on the state of the art to date (1938) may be obtained from the following articles:

# WOODWORKING

By Thomas D. Perry

## 1. MATERIALS

### Logs and Logging

**RIVER LOGGING** formerly was practiced in all forest areas where cold weather facilitated operations by freezing the ground, making roads passable, and where snow aided transportation of logs on sleds to the river side. Logs were decked high at convenient waterways, awaiting Spring freshets that would float the logs to the saw mills. Saw mills had, connected by channel to the river, log ponds for storage and sorting. Logging in the woods was largely a Winter operation; the log drives and jams provided many serious hazards of bridge damage and the risk to the rivermen. Saw mills were most active in the Spring after the arrival of the logs and tapered off in the Fall. Winter logging still prevails in sparsely-wooded areas, often with second-growth timber, but is little used in the far West and deep South.

**TRACTOR LOGGING** was developed because the immense size of trees on the Pacific Coast necessitated mechanical handling of logs, especially as logs up to 40- and 60-ft. lengths were available and desirable for large timbers. The usual practice is to "snake" or "skid" logs by cables. A track cable is attached at one end to a high tree stump, and at the other to a steam or Diesel-driven "skidder." The skidder cable is reeved through a sheave that travels on the track cable, and is attached to one end of the log. The winding drum on the skidder then lifts and drags the logs to a convenient central point, where they are loaded by derrick or small skidders on railroad cars or tractor-trucks. Skidders can operate through a radius of 1000 ft.

Logging railroads usually are temporary, with little grading, and are pulled up and relocated as stumpage is exhausted. Because of excessive grades and curvature, geared locomotives are used. Corduroy roads often are required for truck and trailer operation. Truck and trailers are of several types, trailers with regular or caterpillar tractors, and trucks of the "straddle" type, where logs are hoisted and suspended between the wheels, being common.

**SWAMP LOGGING** often is imperative in the warmer districts where roadways do not freeze. Corduroy roads usually are necessary, with smaller mechanical equipment than on the Pacific Coast, as long logs are few in number, and most logs can be loaded by man power. In the larger swamps, like the Dismal Swamp on the Virginia-North Carolina line, canals have been dug to simplify log transportation, and many mills in such areas are supplied with logs by barge and tug. Logs also are handled by skidders to logging railroads built on crib-work or fills.

**SELECTIVE LOGGING** is obligatory in removing timber from government-owned and controlled areas. Such a policy can make the saw mill and its adjoining homes a continuous operation. It eliminates the inexcusable waste that occurs when a mill "cuts out," and all related real estate values are practically obliterated.

Much of the early logging, and the era is not wholly past, completely cleared the entire timber stand and left almost worthless cut-over land, frequently burned over, which usually reverted to state or national control. The re-establishment of either growing timber or any other useful yield has proved to be very expensive and to require many years. Selective logging is the economically sound practice, which permits the felling of only those trees which will produce merchantable logs, leaving well-distributed and healthy seed-propagating trees for the establishment of a continuous growth. If brush is cleared away and fire kept out, a 20-year stand should produce pulpwood, poles, etc.; a 40-year stand should supply fair-size saw logs, although some species may take longer.

**LOG SCALES** resulted from the attempts of the early timberman to state the amount of lumber that reasonably could be expected from the average log. He endeavored to eliminate the slabs, edgings and saw kerf (see p. 22–34), and to allow for the oversize of board thickness provided for shrinkage during drying. These scales were applied to the small end of the log, and the figures usually stamped thereon. The taper of the log was a factor in some scales, so that a 24-ft. log does not necessarily scale twice that of a 12-ft. log.

From this unscientific and rule-of-thumb beginning, numerous log scales developed, many of them only of local importance. A few which have received definite and wide-spread recognition are given in Table 1 for a log 16 ft. long. Other sizes, under these scales, and other scales can be found in several published woodsmen's handbooks. Fig. 1 is a graphical comparison of the several log scales applied both to sawn lumber and to veneer, using a log 18 in. diameter as an example.

**Table 1.—Comparison of Log Scales, 16 Ft. Lengths**

Cylindrical content $= \frac{1}{4}\pi D^2 \times (16/12) = \frac{1}{3}\pi D^2$ board feet

| Diam., Small End., in. | Doyle Scale | Scribner Scale | Doyle-Scribner Scale | Scribner Decimal Scale | Spaulding Scale | Cylindrical Content |

| " " percent | 137 | 149 | 99 | 107 |
| Spaulding, board feet | 216 | 216 | 216 | 216 |
| " percent | 133 | 145 | 96 | 104 |

Log scales are used both for the purchase of logs, and to estimate timber stands for valuation purposes. An experienced timber cruiser should be employed for the latter. The Spaulding and Doyle scales and their combinations are extensively used in the Midwest and the South; the Spaulding and Scribner Decimal scales are more usual on the Pacific Coast. In general, log scales favor the purchaser, rather than the seller of logs. A good grade of logs should produce the scale footage of lumber and substantial over-runs of veneer.

## Lumber

**SAW LOGS**, suitable for conversion into lumber, usually are those between the selected peelers required for veneer and the smaller logs used for poles, posts, mine props, etc. Small blocks and down-fall are dimensioned into shingle blocks or prepared for gang sawing into lath. One-inch boards usually are cut about 1 $^1/_4$ in. thick to allow for shrinkage, thickness variations, and saw marks. Corresponding allowances are made on other thicknesses. One-inch boards should *dress clean* to $^{13}/_{16}$ in., 2-in. stock to 1 $^5/_8$ in., and 4-in. stock to 3 $^1/_2$ in.

Lumber usually is marketed as *air-dried*, containing between 15% and 25% moisture, and as *kiln-dried*, approximating 10% moisture. While considerable lumber is machined or dressed green, allowance must be made for shrinkage, which may run considerably over 10%. The shrinkage and distortion varies with the position in the log from which a piece is cut. See Fig. 2. Tangential shrinkage is about twice the radial shrinkage. For data on the various species of wood, see p. 5–20.

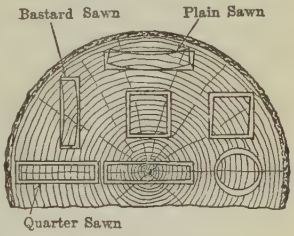

Fig. 2. Effect of Direction of Annual Rings on Shrinkage

**TYPES OF SAWING.**—Logs are sawed in various ways as follows: (See Fig. 2).

**Plain sawn** or flat grain lumber customarily is cut right through the log and nominally varies from a tangent on the growth ring to a 45 deg. angle.

**Quarter-sawn**, or vertical or edge grain, theoretically is cut on a radial line across the growth rings. In practice it may extend to 45 deg. from the radial line. In general, quarter-sawn is more carefully selected and its angular range should be considerably less than for plain sawn.

**Bastard-sawn** is a term usually applied to lumber cut between 30 deg. and 60 deg. to the radial or tangent line. Certain species like white oak, when quarter-sawn, show distinct flake markings from the wood rays (radial), which are somewhat less conspicuous in hickory, elm, sycamore, etc.

**CLASSES OF WOOD.**—The following terms are commonly used to describe different types of wood:

**Sapwood** is a name given to the several layers next to the bark, which usually are lighter in color, less dense and more easily dried than the *heartwood* that forms the center of the tree. The life processes of growth are more active near the bark, and decrease toward the heart. Heartwood is sometimes more valuable for color, as in walnut and red gum. Its density makes it more durable for use as flooring, and, in general, its greater solid content makes it more resistant to decay than sapwood. In some trees the line of color demarcation between heart and sap is not easy to detect.

**Softwood**, in general, means lumber from coniferous trees, usually evergreens.

**Hardwood** refers to lumber from broad-leaved trees. The terms have no reference to the hardness of the wood; *e.g.*, yellow pine, a softwood, is much harder than basswood, which technically is a hardwood.

**Spring Wood** is that portion of the growth ring that is formed the early part of the seasonal growth. It usually is less dense than the *Summer wood*, formed during the latter part of the yearly growth. Summer wood usually is mechanically stronger than Spring wood. A large number of growth rings per inch is desirable from a strength standpoint.

**Factory, Shop and Yard Lumber.**—In general, *factory* and *shop* lumber are intended to be cut up for use in further manufacture. *Yard* lumber is of moderate sizes and intended for general building purposes. *Structural timbers* are relatively large in size, and are selected and graded with reference to strength factors. Table 3 gives the board feet content of various sizes of dimension stock. Trade usage designates 1-in. thickness as $^4/_4$ lumber, 1 $^1/_4$-in. as $^5/_4$ lumber, etc.

**AMERICAN LUMBER STANDARDS** embody provisions for softwood lumber dealing with recognized classifications, nomenclature, basic grades, seasoning standards, sizes, uniform workings, description, measurement, tally, shipping provisions, grade markings, tally cards and inspection of lumber. These standards are in the process of becoming incorporated (1938) in the grading rules of the various lumber associations, and are making possible a more intelligent utilization of standard lumber products as well as a more accurate determination of the most desirable species and grades for any specific use.

**Table 3.—Board Measure Content of Dimension Stock**

| Thickness, in. | Width, in. | Length in inches | | | | | | | | | | Length in feet | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | 4 | 6 | 8 | 10 | 12 | 14 | 16 | 18 | 24 | 30 | 4 | 6 | 8 | 10 | 12 | 14 | 16 |

**Lumber Grading Rules** are promulgated by the various lumber manufacturing associations. They usually are revised from year to year, so that it is important to use the latest edition. Most of the hardwood lumbermen have combined their rules in the publications of the National Hardwood Lumber Assoc. They also make available an inspection service, under the same rules, for all controversial points of interpretation. The softwood lumbermen are grouped in several associations, usually according to species and locality. The more important lumber producers' associations, from whom current grade rule data may be obtained, are:

*Hardwood:* American Walnut Manufacturers Assoc., Chicago; Mahogany Assoc., Chicago; National Hardwood Lumber Assoc., Chicago.

*Hardwood and Softwood:* National Lumber Manufacturers Assoc., Washington; Northeastern Lumber Manufacturers Assoc., New York; Northern Hemlock and Hardwood Manufacturers Assoc., Oshkosh, Wis.

*Softwood:* Northern Pine Manufacturers Assoc., Minneapolis; Short Leaf Yellow Pine Assoc., Columbus, Miss.; Southern Cypress Manufacturers Assoc., Jacksonville, Fla.; Southern Pine Assoc., New Orleans; U. S. Red Cedar Shingle Industry, Seattle; West Coast Lumbermen's Assoc., Seattle; Western Pine Assoc., Portland, Ore.; Western Red and Northern White Cedar Assoc., Minneapolis.

## Veneer, or Thin Lumber

**VENEERS** are thin sheets of wood, which are, excepting a minor amount of sawn veneer, knife cut by various processes. See below. There is no saw kerf waste in knife cutting, rotary veneer being cut continuously from the log (See Fig. 3), and sheets of sliced veneer being cut from flitches, *i.e.*, log sections, in widths as they come, without edging (See Fig. 5). Hence the conversion of logs into veneer utilizes much more of the log than does sawing into lumber. See Fig. 1 and Table 2. The assembly of veneers into plywood distributes wood strength more effectively than does solid lumber. Hence, thinner veneers (in plywood form) provide equivalent strength factors as compared with thicker solid lumber. The four principal types of veneer, distinguished by different cutting processes, are:

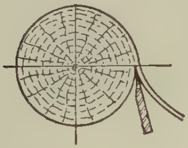

Fig. 3. Rotary Veneer Cut on a Lathe

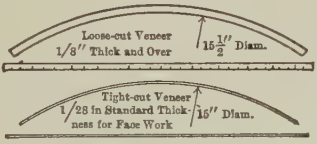

Fig. 4. Tight and Loose Cutting of Veneer

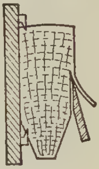

Fig. 5. Sliced Veneer Cut Quartered from a Segment Flitch

**Rotary Veneer**, cut on lathes, accounts for approximately 90% of all veneer. As very little face veneer is made by this process, with such exceptions as birdseye and quilted maple, rotary cut veneer usually is called commercial veneer. It is used for cross bands, cores and faces where strength is more important than appearance. Rotary veneer may be as thin as 0.01 in. It is difficult to cut thicker than $^1/_4$ in., although $^5/_{16}$-in. and $^3/_8$-in. veneer sometimes is cut from softer woods like basswood and poplar. Few veneer lathes are over 8 ft. long (some are 10 ft.) because of the difficulty of cutting accurately across the unsupported distance between lathe centers. Fig. 3 shows rotary cutting, the veneer being unrolled over a knife, much as paper is unrolled. The convex side is the *tight* side and often is marked with crayon during lathe cutting.

Fig. 4 shows tight and loose cut veneer. The cutting checks on the loose side may result from inadequate pressure. They cannot be eliminated entirely, and frequently cause the veneer to flatten better. In some stock, however, they sometimes are objectionable. The process of flattening veneer from its original curved shape need not result in checks or splits on the concave side in veneer under $^1/_8$ in. thick. Proper pressure produces tight cut veneer, and avoids cutting checks. Both sides of the veneer then can be used, as in matched faces. See Fig. 28 for book-matching.

**Sliced Veneer.**—Fig. 5 shows the method customarily used in cutting valuable face veneers. Much of the most attractive face figure, such as mahogany and walnut, is developed from slicing on the "quarter" as shown. Adjacent sheets can be "book-matched" by opening a flitch like the pages of a book, to produce balanced symmetrical figure. Sliced veneer does not have the cutting checks characteristic of rotary veneer. It may be as thin as $^1/_{300}$ in., but seldom can be thicker than $^1/_8$ in. It is regularly cut up to 16 ft. long.

**Half-round Veneer** cutting is an intermediate process between rotary and sliced. Two

**Table 4.—Veneer Dimensions in Inches Reduced to Square Feet**
Fractions of 1/2 or over carried to next higher decimal

| Length, in. | Width, in | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

distinct types are cut, *regular* and *back-cut.* See Fig. 6. Cutting is done in a lathe in which the log or flitch is eccentrically swung between centers on a *stay log*, the radius of knife cut being much greater than in ordinary rotary cutting.

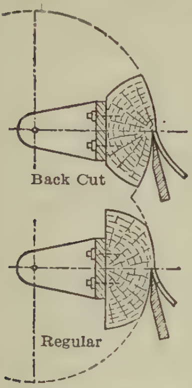

FIG. 6. Half-round Veneer

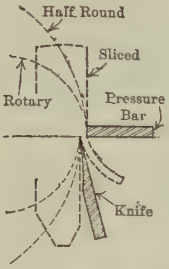

FIG. 7. Positions of Pressure Bar and Knife in Veneer Cutting

Skillful cutting of these three types of veneer depends principally on proper adjustment and manipulation of the relations between the knife and the pressure bar. See Fig. 7.

**Sawn Veneer.**—A few face veneers are sawn on a large diameter segment saw, particularly to reveal the flake of woods like quartered white oak. The minimum thickness for sawn veneer is $^1/_{20}$ in., when the saw kerf waste is equal to the veneer; the maximum may be $^3/_8$ in. or more.

**Standard Thicknesses** for veneer and cutting tolerances are in the process of establishment (1937) by the various associations and the U. S. Bureau of Standards. For description of grade rules and face figure nomenclature, consult the publications of the veneer associations, the more prominent of which are: American Walnut Manufacturers Assoc., Chicago; Mahogany Assoc., Chicago; National Hardwood Lumber Assoc., Chicago; Pacific Veneer Package Assoc., Tacoma, Wash.; Rotary Cut Lumber Assoc., New Orleans; Veneer Assoc., Chicago; Veneer Package Assoc., Washington.

## 2. PRIMARY CONVERSION MACHINERY

### Saw Mills

Saw mills are either permanent or portable. The former are used to saw the timber from large tracts, where the life of the operation will be 10 years or more. The latter are used in small tracts. They are so constructed that they easily can be moved from place to place, and are driven either by steam, gasoline or Diesel engine. Both types of mill use either band saws or circular saws. The former are higher in first cost but the waste in saw kerf is much less.

**ARRANGEMENT OF SAW MILLS.**—Saw mills may be either single or double, *i.e.*, the equipment of a double mill largely is in duplicate, and arranged symmetrically on either side of the center line of the mill. Modern (1938) practice tends to the use of band saws; a mill with one such saw is known as a *single-band mill*; one with two saws is a *double-band mill.*

Fig. 8 shows the arrangement of a typical double-band mill designed to cut 100,000 board feet of lumber per day, with a steam gang saw for sawing baulks of timber into boards. In many mills a horizontal or vertical band-resaw replaces the gang saw. The live roll conveyor arrangement then is somewhat different from that shown. The machinery floor of the mill is elevated 15 to 20 ft. above ground level. Line-shafts or other drives are located below the floor.

Logs are drawn from the log pond or other storage and elevated to the mill floor by a *log slip, i.e.*, an inclined chain conveyor, which may be single or in duplicate. At the head of the log slip, the logs are cut into convenient lengths by a deck saw. This is a horizontal or vertical swing saw, 6 ft. or more diam., belt or motor driven, moved to and fed through the log by steam or air cylinders. Steam-actuated *kickers, i.e.*, steam cylinders whose piston rods terminate in large forked ends, kick the sawed logs from the log slip to the *log deck*, whence they are transferred to the saw carriages. The log deck slopes downward to the carriages, and the logs are moved across it either by gravity or by a power-driven chain-haul. Steam *niggers* transfer the logs from the log deck to the saw carriages, and also turn over the partially sawed logs to present new surfaces to the saw.

The carriages carry the logs back and forth past the band saws. An operator riding on the carriage, by means of appropriate *set-works*, advances the log toward the saw after each cut to obtain the desired thickness of lumber.

The lumber as it comes from the saw is moved by the live roll conveyors and chain transfers to any one of a series of operations. Lumber that is sawed to correct widths moves on the first roller conveyor to the transfer chain to the trimming saws, which cut it to proper length. Lumber which is of irregular width is moved by chain transfers to the double-edgers which cut it to width, whence it passes to the trimming saws. Large baulks of timber are moved by the chain transfers to pass through the steam gang saw which saws the baulk into planks, which then move to the trimming saws.

If a band resaw is used instead of a gang saw, the baulks travel on the first live roll bed to the far end of the mill. A chain transfer then moves them to the middle live roll bed, which returns them in the reverse direction to the band resaw, where they are sawed into boards. The chain transfer moves these boards again to the first live roll bed, which delivers them to the trimming saw.

Refuse from the various operations is disposed of in several ways. Sawdust from each operation drops into a conveyor which moves it either to a fuel storage or direct to the boiler plant. Trimmings, edgings, and other pieces that are large enough are placed on conveyors to transport them to the lath and shingle mills for conversion into marketable product. Other waste is diverted to the slasher which saws it into pieces short enough to be used as fuel. In some mills the slasher delivers it to a fuel hog for further preparation for the boiler furnaces (see Kent's Mechanical Engineers' Handbook—Power, p. 443, forming Vol. 2 of this series).

Finished lumber from the trimming saws is placed on the sorting chain. This is a two- or three-strand chain conveyor from 400 to 800 feet long, on which the lumber is graded and sorted into convenient stacks for transfer to the lumber yard or dry kilns.

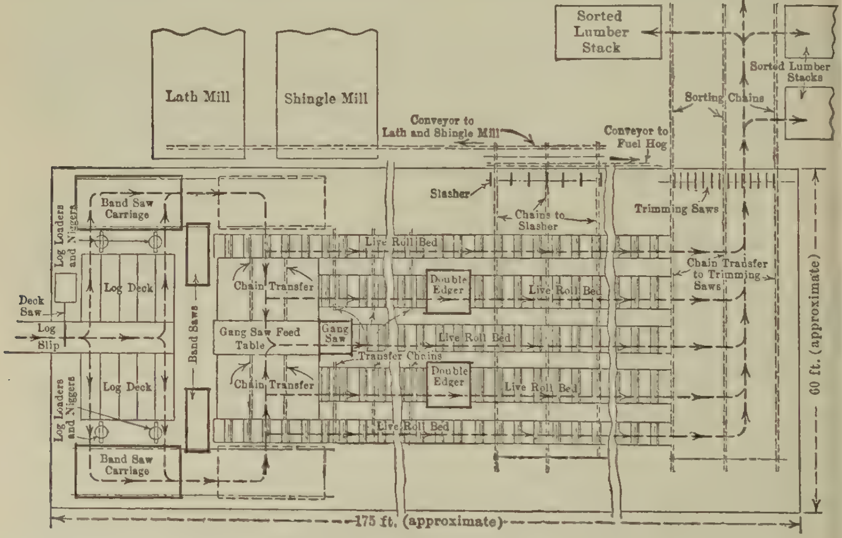

FIG. 8. Double-band Saw Mill

**SAW MILL MACHINERY.**—The following paragraphs briefly describe the various items of equipment commonly used in large saw mills. Manufacturers of equipment should be consulted for detailed specifications and advice concerning the equipment to use for any particular set of conditions.

**Band Mills.**—A band mill comprises a heavy cast-iron frame and column carrying an upper and lower band wheel on which runs a band saw. The upper wheel usually has a cast-iron rim with steel spokes cast in place. The lower wheel sometimes is of the same construction and sometimes is made entirely of cast iron. The shaft and bearings of the upper wheel are movable in a vertical plane for the purpose of putting the proper tension on the saw. Various types of mechanism or *straining devices* are used by different manufacturers to maintain uniform tension on the saw. The mill is driven by a belt pulley on the shaft of the lower wheel.

Band mills commonly are made with band wheels of from 6 to 10 ft. diameter. The diameter of the wheel designates the size of the mill. The saws range from 10 in. wide, No. 16 gage, on 6-ft. mills, up to 18 in., No. 12 gage, on 10-ft. mills. The length of the saw varies with the class of work to be done. For yellow pine, and similar hardwood, a short stiff saw is preferable to one that is more flexible. Fig. 9 and Table 5 give the overall dimensions of Allis-Chalmers band mills. Table 6 gives the capacity and horsepower requirements of these mills.

**Saw Carriages** are massive timber frames carried on 8 to 12 wheels, riding on T-rails. Rails weigh from 60 to 90 lb. per yard. The headblocks, which carry movable knees, are mounted on the carriage. The knees each carry two sets of dogs with teeth pointing upward and downward, respectively. These dogs grip the baulk of partially-sawed timber, and hold it firmly against the knee while the carriage moves it past the saw. Hook dogs on each knee are used to hold round logs against the knee. The number of headblocks depends on the length of logs sawed. Up to 30-ft.

* Low mill. † With babbitted bearings; deduct 20% for roller bearings.

logs, 2-block carriages are usual. For logs over 30 ft. long, three headblocks generally are used. After each saw cut, the log or baulk is advanced the desired amount for the next cut, by means of *set-works* which move the knees forward. The set-works are of varying design, and may be actuated by air or steam cylinders, or by hand. Appropriate mechanism limits the travel of the set-works to a predetermined amount, thereby enabling exact thicknesses of lumber to be cut. Set-works usually are designed to advance the knees by multiples of 1/32 in. The operator rides on the carriage and manipulates the set-works in accordance with directions from the sawyer. Overall width of carriages as made by the Filer and Stowell Co. range from 6 ft. 8 in. to 10 ft. 2 1/2 in. The length depends on the length of logs cut.

Two general methods are in use for traversing the carriage past the saw, *steam* or "*shot gun*" feed and *twin-engine feed*. The former is a steam cylinder from 10 to 16 in. diameter, and of stroke equal to the total travel of the carriage. It is located with its axis on the center line of the carriage. Total travel is determined by the length of the longest log, plus 15 to 20 ft. The piston rod is attached to the carriage. Steam admitted to one end of the cylinder causes the carriage to move the log against the saw. Admitted to the other end, it returns the carriage to its original position.

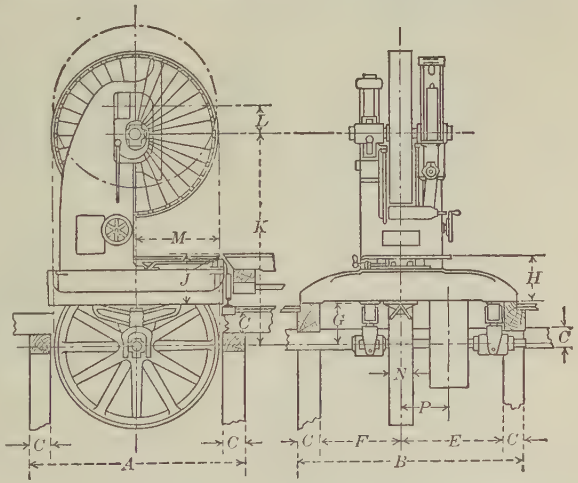

Fig. 9. Band Mill

The twin-engine feed comprises a pair of steam engines, with cranks set at an angle to each other, driving a winding drum either directly or through gears. An endless cable on the winding drum runs over a sheave at the far end of the carriage track and is attached to the carriage. The carriage is moved back and forth by winding or unwinding the cable on the drum. One widely-used type of twin-engine feed has oscillating engine cylinders. The speed and direction of rotation are controlled by valves operated by the sawyer. Cylinder sizes range from 9 × 12 in. to 16 × 20 in., and winding drums range from 27 in. diam. by 11 in. face, using 3/4-in. rope, to 48 in. diam. by 23 1/2 in. face, using 1 1/8-in. rope. Carriage travel up to 200 ft. can be obtained with this type of feed. The twin-engine feed is more economical of steam than the shot-gun feed, but is slower in operation.

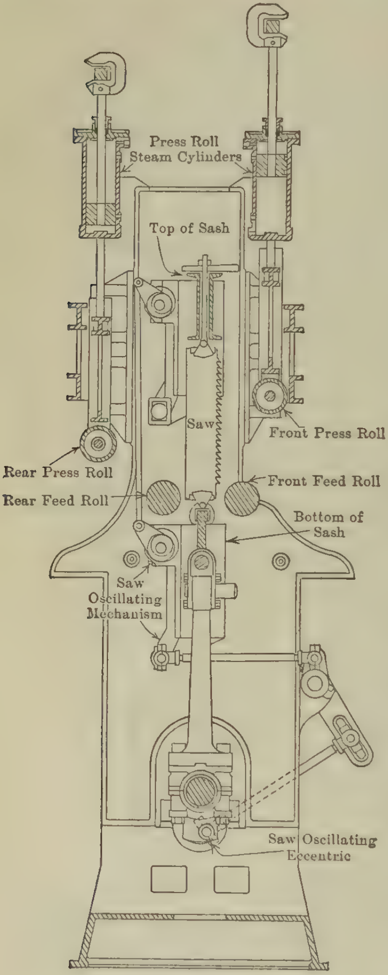

Fig. 10. Gang Saw

**Gang Saws** are reciprocating saws, mounted in gangs to saw large baulks of lumber into a number of planks in one operation. They are either belt- or engine-driven. From 25 to 54 saws are mounted parallel to each other, the requisite distance apart to saw planks of the desired thickness. They are carried in a steel sash which is reciprocated vertically by a pitman driven by a crankshaft below the sash. In the Wickes gang saw, Fig. 10, the saw is oscillated on the down stroke, to vary the depth of cut in accordance with the variation in linear speed of the saw due to the change in position of the crank. This is accomplished by means of an eccentric on the crank-shaft which operates linkwork to move the lower guides of the sash forward at about 5/8 of the upward stroke of the saw, continuing the forward motion until 5/8 of the down stroke has been completed. The guides then move backward, and free the saw from the cut on the return stroke. The path of the saw teeth on the down stroke is an oval, the depth of cut being greatest at the point in the stroke where the linear speed is highest. The amount of oscillation is increased as feed increases, so that the saw always works at maximum efficiency. Work is fed to the saws by fluted feed rolls, driven by a friction feed, whose speed can be varied by the operator at will. Pressure rolls, actuated by steam cylinders, hold the work firmly in place during sawing. Table 7 gives data on gang saws.

**Band Resaws.**—Band resaws are of both horizontal and vertical types. The vertical type is, in general, similar to the band mill, with the exception that it has adjustable feed rolls on either side of the saw to provide for resawing various thicknesses of stock. The feed rolls usually are power operated, and can be set to saw thicknesses varying by 1/32 in.

The horizontal band resaw comprises a massive column supporting on either side of it bearings for the band wheels. The saw blade is horizontal. Underneath the upper run of the saw and at right angles to it are one or two adjustable feed tables which can be raised or lowered to vary the thickness of the stock sawed. Above the feed table, and before and behind the saw, are sets of pressure rolls, independently adjustable, to permit two or more different thicknesses of slab to be sawed at the same time. If but a single thickness of work is to be sawed the feed table is made stationary.

Filer and Stowell Co. gives the following data concerning single-table horizontal band resaws:

| Size of Bed | | Pulley | | | Saw | | Lift of Press, Rolls, in. | Drop of Table, in. | Horsepower |
|---|---|---|---|---|---|---|---|---|---|
| Resaw | Width, in. | Diam., in. | Face, in. | R.p.m. | Max. Width, in. | Gage No. | | | |
| 6 ft. | 36 | 32 | 17 | 420–450 | 10 | 16 | 13 | 4 1/2 | 75 |
| 8 ft. | 36 | 44 | 25 | 320–340 | 12 | 14 | 13 | 4 1/2 | 100 |

Double-table resaws have the same dimensions, excepting that the tables are 16 and 24 in. wide.

**Edgers.**—Double edgers consist of one or more circular saws so mounted on the saw arbor that they can be moved on it in an axial direction. The position of the saws is controlled by the operator, who sets them to cut whatever width of stock may be desired. Double edgers are used to remove the rough or wany edges from slabs to form a single wide plank, or to saw a wide slab into several narrower planks. Saws range from 20 to 24 in. diameter, and usually are direct motor driven through a flexible coupling, although belt drive also is used. Double edgers are made ranging

**Table 7.—Sizes and Capacities of Gang Saws**

(Wickes Bros., Saginaw, Mich.)

| Saw No. | Width between Stiles, in. | Cut, in. | Stroke, in. | Pulley Size, in. | R.p.m., max. | Hp., average | Saws | | Feed, in. | | Capacity per 8 hr., M Board Feet |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | Size, in. | No. | Max. | Min. | |
| 10 | 44 | 18 | 20 | 72 × 25 | 240 | 200 | 8 × 47 | 36 | 1 1/28 | 5/16 | 140–175 |
| 10 | 48 | 18 | 20 | 72 × 30 | 240 | 250 | 8 × 47 | 40 | 1 1/28 | 5/16 | 160–200 |
| 10 | 52 | 18 | 20 | 72 × 30 | 240 | 250 | 8 × 47 | 44 | 1 1/28 | 5/16 | 180–215 |
| 10 | 60 | 18 | 20 | 72 × 33 | 240 | 300 | 8 × 47 | 52 | 1 1/28 | 5/16 | 200–240 |
| 15 | 32 | 8 | 10 | 36 × 8 | 275 | 40 | 4 5/8 × 24 | 27 | 1/2 | 1/8 | 20–30 |
| 16 | 40 | 14 | 15 | 48 × 12 | 250 | 125 | 8 × 37 | 33 | 3/4 | 1/4 | 75–85 |
| 17 | 32 | 10 | 12 | 42 × 10 | 275 | 50 | 5 × 28 | 27 | 1/2 | 1/8 | 25–40 |
| 18 | 48 | 14 | 15 | 48 × 14 | 250 | 150 | 8 × 37 | 39 | 27/32 | 9/32 | 80–100 |
| 19 | 32 | 12 | 13 | 42 × 10 | 275 | 50 | 6 × 31 | 27 | 1/2 | 1/8 | 30–50 |
| 22 | 54 | 14 | 15 | 54 × 14 | 250 | 175 | 8 × 37 | 44 | 15/16 | 5/16 | 90–115 |

from 54 to 72 in. wide in the saw space, and single edgers range in width from 36 to 54 in. wide. Edgers are provided with pressure and feed rolls both before and behind the saws.

**Slashers.**—A slasher consists of a series of saws spaced at equal intervals on an arbor together with feed chains to convey waste material to the saws. Fig. 11 is a diagrammatic arrangement of a slasher. The chains *A* extend across the mill, as shown in Fig. 8, to convey waste from any set of live rolls. The short feeder chains *B* insure that the waste is squarely presented to the saw *C*. The discharge chains *D* normally lie below the plane of the roller conveyor, but when a piece is to be transferred to the slasher these chains are elevated to lift the material from the roller bed and discharge it to the slasher chain. Sawed slashings drop into the conveyor *E* which transfers them either to the lath and shingle mills, or to the fuel hog.

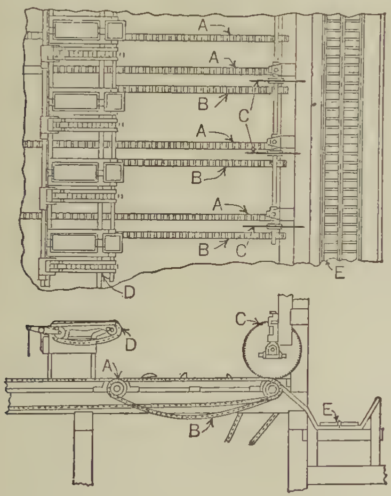

Fig. 11. Diagrammatic Arrangement of Slasher

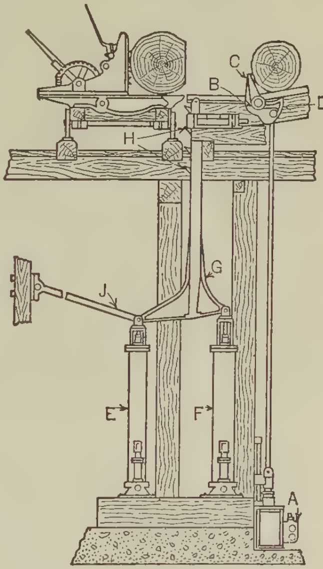

*Filer & Stowell Co.*

Fig. 12. Nigger and Log Loader

**Trimming Saws.**—Trimming saws comprise a series of swing saws suspended over transfer chains somewhat similar to those used in the slasher. The saws are spaced at such intervals that any two of them will saw stock to commercial lengths. In the more modern types of trimming saws, compressed air is used to swing the saw into the path of the work. Each saw is individually controlled by one operator, who, as a piece of stock approaches the saws, depresses those two which are nearest to the ends of the stock. The trimming saw conveyor delivers the sawed stock to the sorting chain.

**Niggers and Log Loaders.**—Fig. 12 shows, diagrammatically, a steam nigger and log loader. The log loader comprises the steam cylinder *A* connected to the loader arm *B*. The nigger consists of the oscillating steam cylinders *E* and *F*, the head *G* carrying dog-teeth *H*, and the radius rod *J*. Steam to the cylinders is controlled by suitable valves, operated by the sawyer. The log is held at the edge of the log deck by the arm *C*. When steam is admitted to cylinder *A*, arm *C* is rotated downward and arm *D* kicks the log against the knee of the saw carriage. The head *G* of the nigger then is raised by the cylinders *E* and *F* until the teeth *H* engage the log. The direction of motion of the head is controlled by the combination of the radius rod *J* and the variable stroke possible in the two cylinders *E*, *F*, to hold the log in place until it is gripped by the carriage dogs or to turn it through any desired angle.

Log loader cylinders range from 8 to 18 in. diameter, with stroke varied to conform to log sizes. Nigger cylinders range from 8 to 14 in. diameter, with stroke of 5 to 6 ft.

**Manufacturers.**—Saw mill machinery is built by Allis-Chalmers Co., Milwaukee, Wis.; American Saw Mill Machinery Co., Hackettstown, N. J.; F. L. Estes Saw and Machinery Co., Nashville, Tenn.; Filer and Stowell Co., Milwaukee, Wis.; Gainesville Iron Works, Gainesville, Ga.; Standard Saw Mill Machinery Co., Erie, Pa.; Taylor Iron Works and Supply Co., Macon, Ga.; Wheland Co., Chattanooga, Tenn.; J. A. Vance Co., Winston-Salem, N. C.

**SAW MILL DRIVES.**—Saw mills are, in general, driven either from one or more line-shafts extending the length of the mill, underneath the machinery floor, or by electric motors driving machines individually or in groups. In line-shaft drives, the main shaft is belted to a steam engine or electric motor. Sometimes a rope drive is used to transmit power from the engine. Where the driven machine is at an angle to the line-shaft, mule pulley drives (see p. 24–26) or large bevel gears with wood teeth, or bevel friction gears (see p. 14–03) are used to change the direction of the power supply. Final drive to the individual machines usually is by belt. Line-shaft speeds are from 150 to 250 r.p.m. Line-shafts usually are carried in rigid post bearings. In the more modern mills, all bearings are force lubricated from a central point by an oil pump, reservoir, and oil filter.

Steam engines used for line-shaft drive are of various types. In Southern mills, Corliss engines are widely used. Slide valve engines and uniflow engines also are in use. Steam economy seldom is given consideration in saw mill practice, as wood waste is used for fuel, and usually there is more available than can be burned for steam making. However, it should be remembered that wasteful engines require a larger boiler plant, with consequently greater first cost and overhead and operating charges. Many mill engines exhaust direct to atmosphere and use live steam in the dry kilns, but this practice also requires greater investment in boilers, than where exhaust steam is used in the kilns. A few mills, which have ample water available, operate condensing, and use live steam in the kilns.

**Power Requirements.**—The power required to drive a saw mill with line-shafts varies widely with the type of equipment, the character of maintenance and other factors. A mill of the type shown in Fig. 8 usually would have installed engine capacity of about 1000 hp. Indicator cards from engines driving several mills of this type showed a maximum demand of 850 to 900 hp.

Where the mill is to be motor-driven, manufacturers of equipment will advise as the size of the motors to be installed. For line-shaft drive, the power must be estimated from previous performances of similar mills. The following figures were used in estimating the requirements of a double-band mill, similar to that shown in Fig. 8. They are given as a general guide only, and should be checked against local conditions. The figures are indicated horsepower except as otherwise stated. Deck saw, 30 Hp.; 8-ft. band saw, 225 Hp.; 48-in. gang saw, 225 Hp.; 72-in. double edger, 150 Hp.; slasher, 50 Hp.; trimming saw, 40 Hp.; chain transfer to gang saw, 5 Hp.; chain transfer to trimming saw, 15 Hp.; nigger, 40 boiler Hp.; shot-gun feed for carriage, 14 in., 120 boiler Hp., 12 in., 80 boiler Hp. The load factor generally is taken as 80%.

## Veneer Lathes and Slicers

The accuracy requirements of veneer cutting demand more careful log preparation than for lumber sawing. Logs for rotary cutting are cut to length on a *drag saw*, blade, circular or band. The short lengths, or *bolts*, are sorted by length and specie, and placed in vats for cooking or steaming. To produce sliced, half-round and sawn veneer, logs are sawn into flitches, partly to obtain face figure and partly to facilitate clamping on the machine bed. Every veneer mill producing these latter types requires a small band (band-saw) mill both for flitching and to salvage lumber from unsuitable and defective logs that will not make veneer. Flitching technique varies widely according to log shape and veneer character. Fig. 13 shows a suitable method of flitching oak logs, 24 to 30 in. diameter, for quartering. In crotches, stumps and burls, only experience and judgment can solve the widely varying individual problems of flitching. Flitches, except for the sawn veneer, go to the vats.

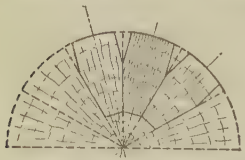

Fig. 13. Flitching for Quarter-sawed Veneer

**COOKING OR STEAMING.**—A few species of veneer woods, as basswood, poplar and similar woods, are best cut "cold," without cooking. All logs are improved for veneer cutting by soaking in a log pond. The best authorities advocate cooking logs in hot water. Temperature and duration of cooking vary widely with the species, size, texture and fresh-ness from the woods. A minimum is 4 to 6 hours at 200° F. up for coniferous woods, extending to 15 to 20 hours at 150° to 175° F. for hardwoods. Flitches of fragile figure are best soaked for longer periods at 100° to 125° F. Too much cooking produces "fuzzy" veneer. Logs are barked before mounting and should not be more than 30 minutes from vat to machine. Some operators prefer steaming, a shorter and more intense process that is too harsh for fragile woods, and one which does not properly penetrate others.

A cooking vat should be built of concrete liberally reinforced, especially at corners, to withstand severe temperature strains. It usually is made about 6 ft. deep by 10 ft. wide; the length is varied to suit capacity. Covers are preferably of steel plates with central rings, and are handled by the crane used for bolts and flitches.

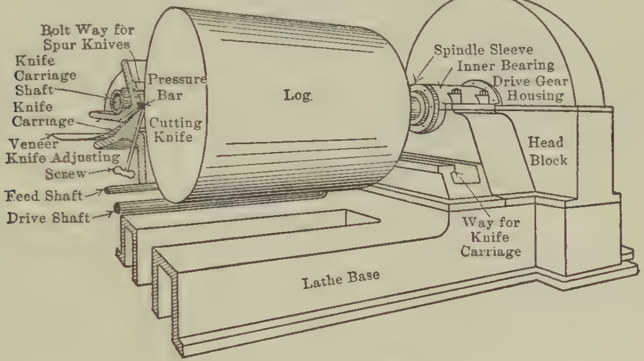

FIG. 14. Veneer Lathe

**VENEER LATHES.**—Fig. 14 shows a typical rotary veneer lathe with one end omitted. Details of the cutting mechanism are shown in Fig. 16. Logs are mounted in the lathe from the back by crane. Standard operating speed, traditionally, is 25 to 30 r.p.m. to accommodate 30-in. logs. This is slow for small logs. Spindle chucks or centers usually are 5- or 6-in. diameter for 60- to 100-in. bolts, leaving a 7-in. core, that is defective in many species, but which sometimes can be cut into crating. Lathes usually are equipped with 50- to 75-hp. motors for 60- to 100-in. lengths and logs up to 30-in. diameter. For larger logs, as on the Pacific Coast, power demand will be greater. An efficient set-up would be mechanical speed control permitting speeds to be changed without stopping lathes, giving 48, 36, 30 and 24 r.p.m., and permitting linear veneer delivery speeds of 100 (for thick veneer) to 200 ft. per min. Electrical speed controls are to be avoided, as motors incline to race under wide load variations, caused by thick and thin cuts, and large and small logs. Table 8 shows the resulting delivery speeds in such a set-up. Rotary box veneer often is cut at 60 r.p.m., but quality requirements are low. Fig. 17 shows a typical lathe lay out, with delivery tables, clipper, and crew location. In

FIG. 15. Veneer Slicer

**VENEER SLICER.**—Fig. 15 shows a typical veneer slicer. Flitches are mounted on the table or bed by dogs, the table moving up and down on angling ways to produce a shear cut. The cutting stroke is about 3 ft. long. The draw or lateral movement of the knife is about 1 1/2 ft. Cutting is done on the down stroke, and the log is fed forward on the return stroke of the knife. Horizontal slicers are used more in Europe than in the U.S., and afford greater latitude in range of angle cuts, often desirable in highly figured flitches. Veneer delivery equipment for slicers is simpler than for lathes. Flitch-cut veneer always is kept in sequence to permit matching.

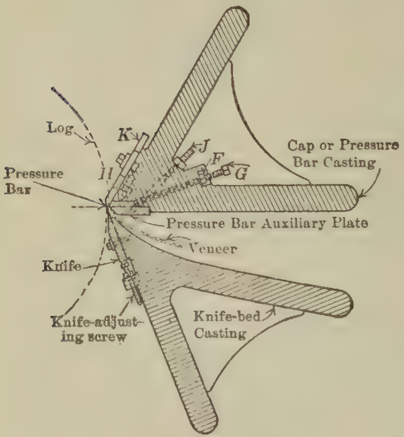

FIG. 16. Details of Veneer Lathe Cutting Mechanism

**HALF-ROUND VENEER** is an intermediate method between rotary and sliced veneer. The log is flitched or sawn, as in slicing, and cooked. It is cut on a lathe provided with a *stay-log* swung from the lathe centers, with radial adjustment and provided with a table or bed to which flitches are clamped with bolts. See Fig. 6. The purpose of half-round veneer is to obtain a veneer with more regular grain than that of rotary veneer.

**CUTTING MECHANISM**, Fig. 16, is essentially the same in both lathes and slicer Its proper adjustment and manipulation is the critical factor in good veneer cutting. The feed mechanism in both lathes and slicers is mounted on two screws, moving the lathe carriage with the cutting mechanism into the log or flitch a distance equal to the veneer thickness at each revolution or stroke.

Rotary veneers usually are cut to widths, providing whole, half, third and quarter parts of the desired sizes. Flitch veneers are kept together after numbering and taking several sample swatches from top, center and bottom of each flitch.

**VENEER DRYERS** comprise rollers, traveling plates or mesh belts, on which veneer passes progressively through drying chambers. Controlled temperature and humidity establish the necessary moisture deficit to dry various thicknesses at a single pass, the speed for thicker veneers being reduced. Veneer usually is dried to 10% moisture content. It must be dried within a few hours after cutting in order to prevent discoloration.

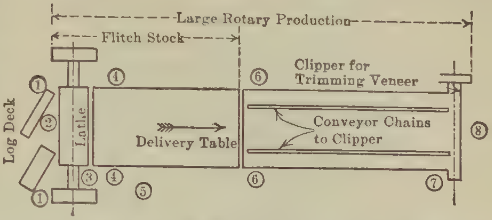

Fig. 17. Standard Veneer Layout and Crew. Standard Crew is: (1) 2 log peelers. (2) 1 log hanger. (3) 1 lathe operator. (4) 2 off bearers or breakers. (5) 1 waste collector. (6) 2 off bearers for large production. (7) 1 clipper operator. (8) 1 clipper off bearer.

## 3. PROCESSING

### Lumber Dry Kilns *

**EQUILIBRIUM MOISTURE CONTENT.**—Wood products, in service and storage, should have, as nearly as possible, an equilibrium moisture content in the wood parts, to keep at a minimum dimensional changes (shrinkage and swelling) due to moisture changes. Under ordinary room conditions this is about 6%–8% moisture content; in normal outdoor weather from 10%–15%. Lumber is stronger and stiffer when dry than when wet. Dry wood (to the extent mentioned above) will retain paint and finishes, whereas wet lumber will not hold surface coatings. Table 9 gives conditions for maintaining moisture content equilibrium in lumber. Correct atmospheric conditions are particularly important in raw lumber storage rooms.

**LUMBER DRY KILNS** are of two principal types. In the single charge (*box* or *compartment*) kiln, the lumber charge remains stationary during the drying cycle; in the *progressive* kiln the lumber moves in the kiln through the various stages in the drying cycle, from the initial low-temperature-high-humidity condition to the final high-temperature-low-humidity stage. Fig. 18 is a comparison of the two types.

**Table 9.—Variation of Equilibrium Moisture Content of Wood**

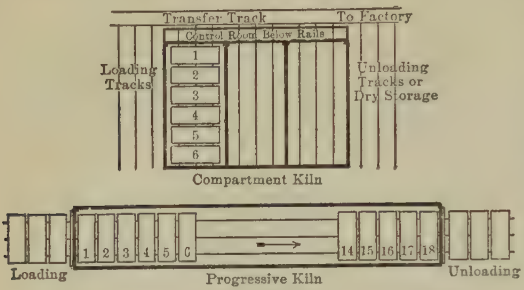

FIG. 18. Dry Kilns with Equal Capacity

**Drying Technique** is of three principal forms, shown in Fig. 19: 1. Natural circulation or *ventilated kilns*, where air movement is accomplished by gravity; 2. Forced circulation, or *fan kilns*, in which air is mechanically forced through the lumber (circulation frequently reversible); 3. *Condensing kilns*, where moisture-laden air passes over condensing coils (usually circulating cold water pipes), is reheated, and again passes through the lumber. Most kilns have steam or water sprays to maintain the humidity. Temperature and humidity controls, usually with recording attachments, are essential to maintain schedule requirements. In kiln drying programs, *humidity* refers to air conditions, and *moisture content* means the moisture contained in the lumber. The latter is computed by weight, weight of dry wood being divided into the weight of moisture removed.

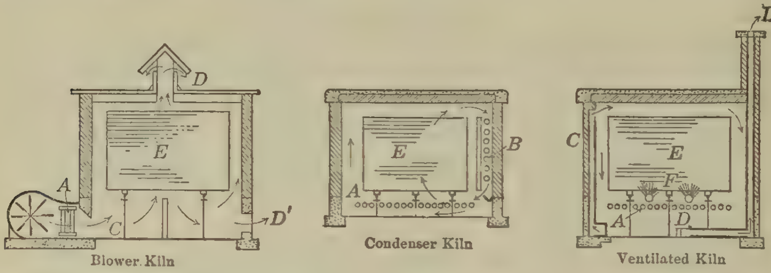

FIG. 19. Types of Kilns. *A*, heating unit. *B*, condensing unit. *C*, fresh air inlet. *D*, *D'*, used air outlets. *E*, lumber charge. *F*, humidifying unit

| Willow | 5 | 6 | 7 | 8 | 8 | 9 | 10 | 12 | 10 | 12 | 14 | 16 |

In general, temperatures of 200° F. safely can be used on 1-in. (4/4) softwoods; for hardwoods the temperature range is 150° to 160° F. With thicker and greener lumber these temperatures must be reduced. Fig. 20 is a convenient chart for atmospheric humidity.

Example.—Determine the relative humidity of air when the dry-bulb temperature is 140° F., and the wet-bulb, 120° F. Enter the chart on the 120° wet-bulb line and follow it until it intersects the curve of 140° dry-bulb temperature. The ordinate through the intersection intersects the relative humidity scale at 54%.

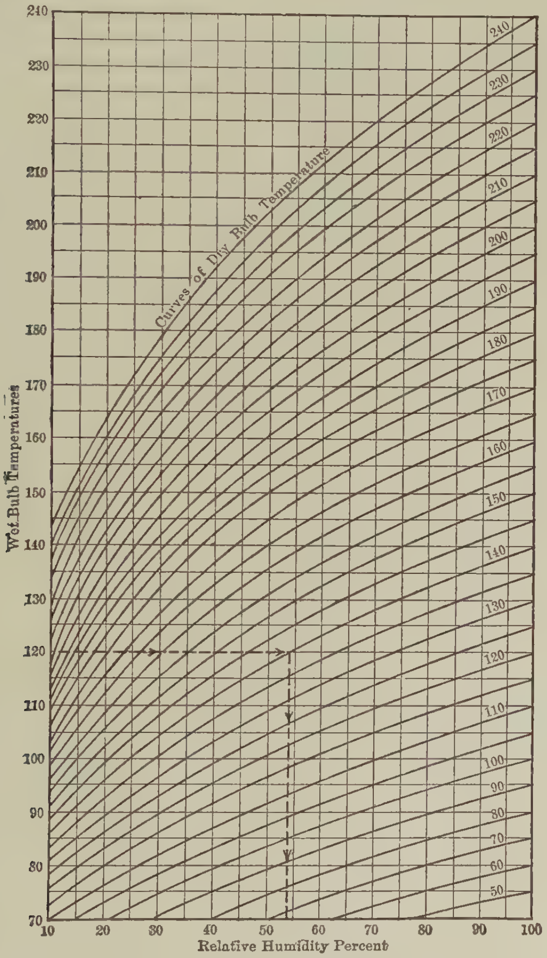

Fig. 20. Relative Humidity Chart

**TIME REQUIRED FOR KILN DRYING** of pine and similar softwoods usually is from 3 to 5 days, from the original tree condition of greenness to about 10% moisture content, usually considered shipping dry. Hardwoods require varying times, according to thickness, original and desired moisture content, and types of kilns available. A general survey of these drying times is given for ventilated kilns in Table 10.

It is highly important that lumber be uniformly kiln dried to the required moisture content, and be maintained at that point during the entire product manufacturing procedure. In fact, most kiln authorities advocate kiln drying slightly below required conditions, and allowing reabsorption to equilibrium point in dry storage.

**Tests for Moisture Content** usually are made by weighing samples. When tests are required, samples are cut from test boards whose locations in the kiln load are shown in

Fig. 21. The locations of the test samples in the test boards are shown in Fig. 22. The board ends, which probably are over-dried, are discarded. Fig. 23 shows the best procedure for marking weighed samples for filing, the figures on the left being moisture content and those on the right shrinkage. In both cases the upper figures are values immediately after cutting test samples; the lower figures are values after oven drying to minimum obtainable conditions, *i.e.*, bone dry. Fig. 24 illustrates a test sample prepared to show case-hardening. If the prongs flare out, the sample is case-hardened but dry; if they pinch, it was case-hardened before drying, and the stresses were not relieved during drying. A further test for exterior and interior moisture content is shown in Fig. 25. The test sample is band sawn, and outer and inner portions weighed before and after oven drying to determine the moisture content of each. A normal moisture content gradient usually will show an excess of 1% to 2% for the inner section.

Table 11 gives data for determining moisture content of veneer and lumber.

**Kiln Accessories.**—For kilns and adjoining storage tracks, 35-lb. rail generally is used, supported at 6-ft. intervals. Kiln bunks or trucks should have roller bearings, frequently lubricated because of the heat. Kiln transfer cars will facilitate lumber distribution from railroad unloading siding direct to kilns, and from kilns to dry storage and cutting rooms. They are usually about 12 in. high, rail top to rail top, and preferably are motor driven. Lumber lifts elevated by motor-driven revolving screws, in a pit below, are essential both for loading and unloading kiln cars, as well as for keeping the top of the lumber load at convenient height for serving rough planers or cut-off saws. Some mills use locomotive cranes with 40-ft. booms to transfer lumber in packets to and from kilns and lumber piles in the yard.

## Machine Operations and Lay Outs

In wood products factories, machine and department arrangement are substantially similar in major items, with considerable divergence in minor details, because of difference in character of products, and degree of pre-manufacture in raw materials. A typical example of standard procedure is given in Table 12.

For further details of plywood and finishing, see below. For kiln drying, see p. 22–17. For details of operation of the other types of wood-working machines, see pp. 22–39 to 22–48.

## Plywood and Gluing

**PLYWOOD.**—Standard plywood consists of an odd number of layers of veneer, with opposed grain in alternate layers, rigidly glued together. The along-the-grain strength reinforces the across-the-grain weakness, and distributes wood strength in both directions. The central layer (core), of veneer or lumber, has the lengthwise grain in the direction requiring strength. In 5-ply, face and core grains are parallel; in 3-ply, they are opposed.

Inspection stations according to product requirements

* Omit plywood operations if plywood is purchased

Fundamentally the layers should be balanced on the core to avoid uneven stresses. See Figs. 26 and 27. The face wood is chosen for appearance; the other layers supply the strength. For most purposes $^{1}/_{4}$-in., 5-ply plywood is stronger than $^{13}/_{16}$-in. solid lumber. Plywood is unsplitable, and has more nail and screw holding power than solid wood.

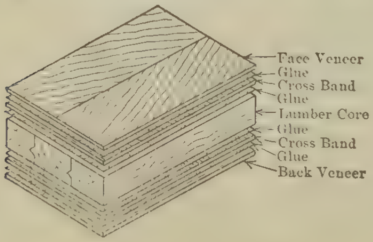

Fig. 26. 5-ply Plywood

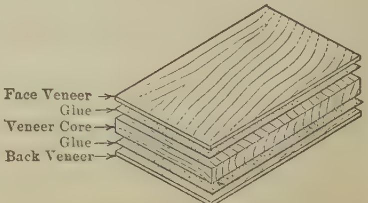

Fig. 27. 3-ply Plywood

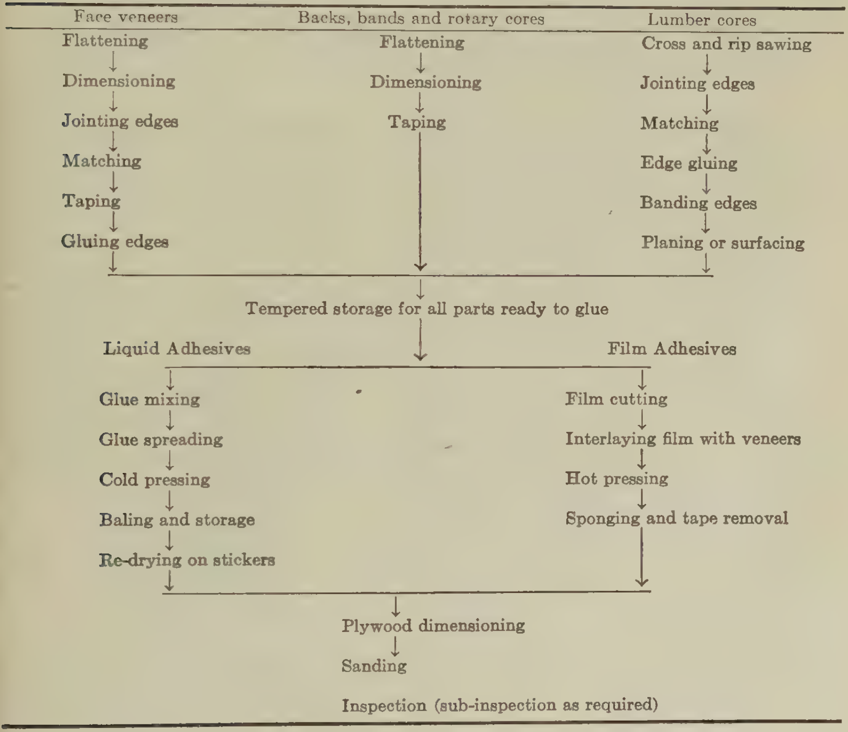
**ARRANGEMENT OF EQUIPMENT.**—Plywood manufacturing falls in two general classes: 1. Factories assembling plywood as a semi-raw material for others; 2. Factories making the ultimate product, as furniture, with an integral plywood department, in which plywood operations are seldom complete. Plywood factories preferably are located with reference to the supply of the bulkiest material, *i.e.*, rotary commercial veneer and core lumber, the face veneer supply being far less important. Propinquity to a consumer furniture area is a doubtful advantage, because of the higher wage levels.

Table 13 shows the general sequence of plywood operations. The face veneer preparation, commercial veneer preparation and lumber core stock converge to a central tempered-air stock-room, where the gluing allocation for each day must be ready not later than the night before. The glue room is invariably the bottle-neck, has a higher man-hour-ratio per machine than any other plywood operation, and must produce at maximum efficiency.

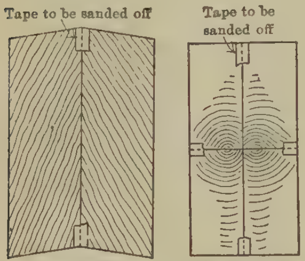
**Table 13.—General Arrangement of Plywood Operations**



**FACE VENEER.**—Sliced, half-round and sawn face veneers are received in flitches, and their suitability for the job in question demands experienced judgment. Unused portions of flitches (lay-backs) are a serious problem, often because of wrong size or figure. In general, whole flitches should be charged to a job, leaving lay-backs as a by-product; otherwise costs may be seriously distorted.

Highly-figured face veneers, if "crinkly," must be flattened before dimensioning. For less fragile species, platen veneer driers are used; it is advisable to dampen fragile veneers and apply gradual pressure with heated boards; in extreme cases, as feathered crotches, veneers are dipped in a dilute glue size to make them more leathery, and are flattened even more gradually. Moisture content should be 5% to 6% after flattening.

Longwood veneers, longer flitches in moderate figure, usually are cross cut on saws in packages of 25 sheets, and edge-clipped (sheared) with reference to figure matching. Clipped edges are *jointed* (see Veneer Jointers, p. 22–43), planed straight and square, to produce tight joints without cracks. *Stumps* (butts), *crotches* and *burls* and other highly-figured veneers usually are cut both ways in packages on a paper cutting machine, with an angling shear cut under pressure. Such veneers cannot be jointed as the edges wil tear out.



*a* Two piece Center Matched
*b* Four piece End and Side Matched

Fig. 28. Matched Veneer

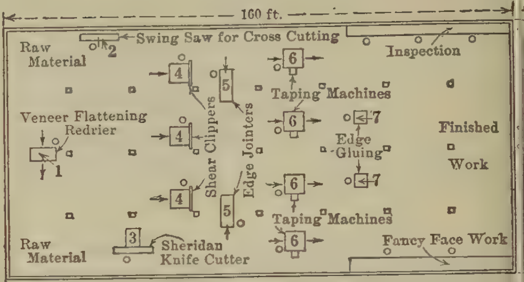


Fig. 29. Arrangement of Face Veneer Department. O indicates position of operator. Numerals show sequence o operations

**Book-matched Veneer** comprises two or four adjacent sheets of a flitch, with uniformly (as to grain figure) trimmed edges, laid together to balance the figure as in Fig. 28. It resembles an unfolded 2- or 4-sheet booklet.

**Dimensioned Veneers** (longwood or book-matched) are *taped* (see Fig. 28) with gummed tape from edge to edge on one surface to hold the pieces in position during gluing. The tape is sanded off later. Taping machines have angling rollers that draw the edges together and press the moistened gummed tape over the adjoining edges. Intricate *combination faces*, of vari-colored species, with or without angling grains, give remarkable effects. Fig. 29 shows general arrangement of machine operations in a face veneer department.

**CROSS-BANDS, ROTARY CORES AND BACKS,** unless two faces are required, are of commercial rotary veneer, flattened, edge-clipped, sometimes jointed if 3-ply, and taped as in face veneer, but without regard to figure. Cross-bands under faces, as well as cores in 3-ply plywood, should be one-piece and not taped, as tape will show through. Back cross-bands, backs and 5-ply cores may be taped. Commercial veneers, for long runs of standard sizes often are dimensioned at the veneer mill into whole, half, one-third, two-third, one-quarter and three-quarter sizes for taping. Moisture content must be kept close to 5%, except that certai layers in film bonding should be 8% to 12%. A commercial veneer department arrangement would be similar to Fig. 29, omitting the swin saw, Sheridan cutter and edge gluing.

Single Double Dovetail Joints

Fig. 31. Types of Edge Joints in Plywood Cores

**LUMBER CORES** generally are used for plywood ½ in. and thicker. Five-ply construction i the more stable; face and back veneers in 3-pl usually are thin and do not effectively balance th lumber core. Core lumber is preferably of popla chestnut, gum, or other available species. Only on species should be used in a core. Chestnut doe not give a sound edge for molding or shapin To avoid warp, cores preferably should be mad of strips 2 to 3 in. wide. End joints are not objectionable and tend to eliminate twisting stresse Fig. 30 shows various core constructions, and Fig. 3 various core joints. The dotted lines in Fig. 3 indicate multiple cores to be cut apart after planin or gluing, to avoid showing endwise splices. The veneer strips used as glue carriers in co e are patented.

Fig. 32 shows the arrangement of a core department. Lumber is most economically handled on kiln cars from dry storage and placed on a lumber lift; top of load then always is at machine table height. If, before cross cutting, both sides are rough planed to reveal defects, a 2-side rough planer is placed adjacent to the lift, with the swing cut-off saws next in line. The stock then goes from cross-cut to rip-saws (see pp. 22–35 and 22–39) for trimming edges and removing wane (tapered and bark edges). If specifications are not too exacting, ripped edges may be glued together without further finishing operations, but quite frequently edges must be jointed true, straight and smooth for gluing. The sliding matching table, operation 5, is used for the purpose of arranging core strips to distribute stresses, and to rip the last strip to net core width.

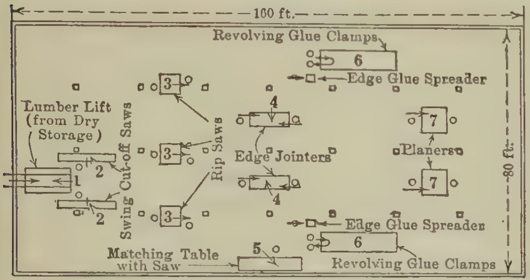

Fig. 32. Arrangement of Core Department. O indicates position of operator. Numerals show sequence of operations.

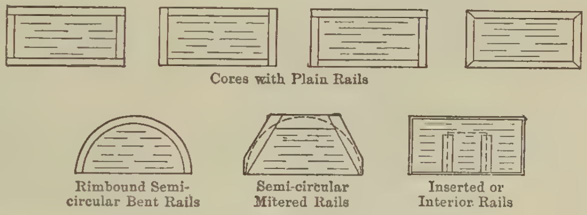
Assembled core strips are glued edge to edge in an endless chain revolving clamp, with a cycle of about 30 minutes. When the glued core returns to the loading point, it is removed and a fresh assembly inserted. The application of edge glue swells the lumber, increasing thickness at the joint, and glued cores should be seasoned, or equalized in moisture content, before planing.



Cores with Plain Rails

Rimbound Semi-circular Bent Rails

Semi-circular Mitered Rails

Inserted or Interior Rails

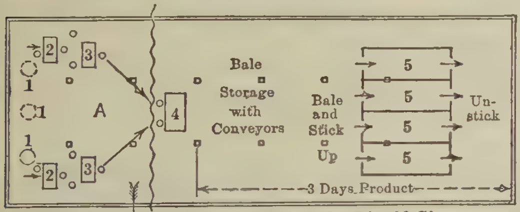
Fig. 33. Banded or Railed Cores

**Banded or Railed Cores** (Fig. 33) have a band or rail, of the same species as the face veneer, on one or more edges, to give molded edges the same appearance as the upper surface. These bands are additional core strips, glued on edges or ends, after the ends are trimmed.

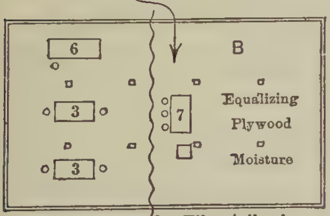
All plywood elements, faces, bands, backs and cores for an order should meet in an air-conditioned central stock room to avoid subsequent glue room delays.

**PLYWOOD GLUING DEPARTMENTS** are of two distinct types: 1. Adhesives are mechanically mixed and spread in *liquid* form as layers are assembled. 2. Adhesive films are merely interleaved between the layers of veneers. The two types of department are shown in Fig. 34.

**Liquid Glues** are: 1. *Animal* (bone and hide), prepared and spread hot. Seldom used because of cost. 2. *Vegetable* (casava or tapioca flour), cooked with caustic during mixing, and spread cold; used for cabinets and furniture, where water resistance is not required. 3. *Casein* (self-soured or acid-soured curds of milk), mixed, and spread cold with 5% to 15% of hydrated lime; water resistance increases with lime content, but similarly adds abrasive qualities that dull tools. 4. *Soya bean* (flour from soya bean residue after oil extraction), mixed with caustic, and spread cold; used



Arrangement for Liquid Glue with Cold Pressing



Arrangement for Film Adhesive with Hot Pressing

Fig. 34. Plywood Gluing Department. O indicates position of operator. Numerals show sequence of operations

chiefly for box shooks and cheaper plywood. Some minor use is made of *liquid glass* (silica) and *fish glues*. Resin adhesives are a comparatively recent development which are coming into extensive use. They are more fully described below.

*Glue Mixers*, except for animal glue which is heated without mixing, are steam- and water-jacketed, and have revolving double beaters. They usually are located above the spreaders and discharge into them.

*Glue Spreaders* usually coat both sides of veneer at one operation; they have corrugated steel rollers provided with scrapers (doctor bars or rollers), with glue reservoirs for both rolls. The spread veneer is *laid-up* with alternate layers of unspread veneer or lumber, until a 3-ply or 5-ply unit is complete. Assembled units often are separated, singly or in pairs, by *cauls* (waxed plywood or fiber sheets).

When as thick a *bale* or *package* has been accumulated, as will enter the daylight of the hydraulic press, the charge is pressed with 75 to 100 lb. per sq. in. of plywood area. While still under pressure, I-beams and clamp bolts are attached to maintain pressure until the initial edge glue set has taken place, usually from 4 to 12 hours. Clamped bales weigh 500 lb. and more, and are best handled by overhead conveyors. They usually are stored over night and opened the following morning.

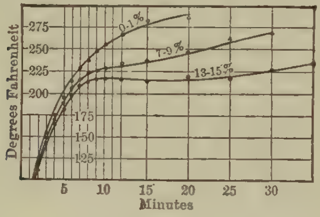


FIG. 35. Temperatures Attained with Veneers of Different Moisture Content During Different Pressure Periods. Platen temperature (P.T.), 300° F. Core thickness, 1/4 in. Specific pressure, 150–200 lb. Penetration depth, 3/8 in.

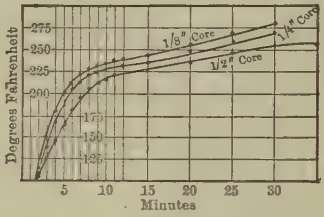

FIG. 36. Temperature Attained with Various Core Thicknesses During Different Pressure Periods. Platen temperature (P.T.), 300° F. Veneer moisture content 7–9%. Specific pressure, 150–200 lb. Penetration depth, 3/8 in.

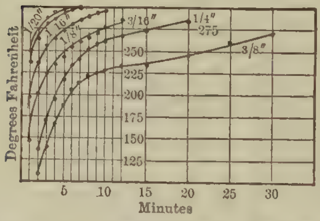

FIG. 37. Temperatures Attained with Various Penetration Depths During Different Pressure Periods. Platen temperature (P.T.), 300° F. Veneer moisture content, 7–9%. Specific pressure, 150–200 lb. Core thickness, 1/4 in.

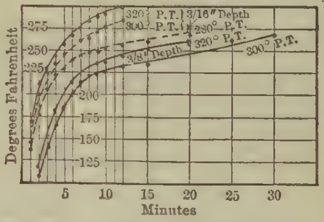

FIG. 38. Temperatures Attained with Various Platen Temperatures and Penetration Depths during Different Pressure Periods. Specific pressure, 150–200 lb. Veneer moisture content, 7–9%. Core thickness, 1/4 in. P.T. = platen temperature.

The resulting plywood has excessive moisture content, due to glue water. It should be *re-dried* in an air-conditioned room at 100° to 120° F., and 70% to 50% humidity for about two days. Re-drying plywood should be piled with alternate layers of uniform stickers to give full surface exposure for easy moisture removal, and well weighted down during re-drying to prevent warping. Cheaper grades of plywood, as plywood box shooks, where gradual evaporation of moisture content and consequent warping are unimportant, need not be re-dried.

**Resin-film Adhesives** are thin sheets of tissue paper, coated on both sides with synthetic resins. They have been successfully used in Europe for 10 years and made in the U. S. since 1935. Typical and most used of these, Tego, is a phenol formaldehyde resin. It comes in continuous rolls, is cut to veneer sizes, interleaved with veneer on a *lay-up* table, and sometimes held in position by gummed tape or wire staples. It is immediately ready for pressing, requiring simultaneous heat and pressure for setting or *polimerization*. Setting of the resin film makes the resulting joint insoluble in water, and produces the strongest plywood bond known, such as is required for airplanes and other uses exposed to weather. Required temperatures are from 280° to 300° F. Specific pressures on the plywood range from 150 lb. per sq. in. up, depending on the compressibility of the wood species. Hot presses are hydraulically operated and equipped with from 6 to 11 steam (occasionally electrically) heated platens. Each hot press opening normally will take one layer of assembled plywood; but it often is practicable to insert two or more layers, up to $^1/_8$ in. each. The time required for heat penetration usually precludes more than $^3/_8$ in. total thickness in each press opening. Plywood is conveniently placed between sheet aluminum *cauls* (No. 16 gage) to facilitate press loading. Alternate veneer layers, usually the crossbands, should have 8% to 12% moisture content to aid in the initial flow of the resin as it becomes heated. Further heat and pressure give the final set. Figs. 35 to 38 show the speed and extent of heat penetration to the furthest adhesive line to be polimerized. It is important that the effect of the variables be carefully observed to obtain the best results in film bonding. After removal from the press, plywood only requires cooling under slight pressure, to be ready to dimension. Some authorities prefer to cool and restore normal moisture content in the plywood by dipping or spraying with water. See Fig. 34.

**Liquid Resin Adhesives** are (1937) coming into accepted use. They are mixed and spread as described for liquid glues, and bonded in hot presses. While having a urea formaldehyde base, lacking the full waterproofness of film adhesives, and requiring more processing than films, they can be extended by admixtures, and thus are considerably cheaper than films. A departmental lay-out can be had by adding section A of Fig. 34 to section B, following the arrow.

**PLYWOOD DIMENSIONING** preferably is done on double cross-cut and double rip-saws of the double-end tennoner type (see p. 22–46), in which a pair of endless chains, with lugs, carry the plywood through the saws. One saw head is fixed and the other adjustable to the size required, usually up to 72 in. Many other types of saws and saw tables may be used for this work. Ripping usually precedes cross-cutting. For center matched plywood faces, pointers on the machine are used to insure proper centering of face veneer joints.

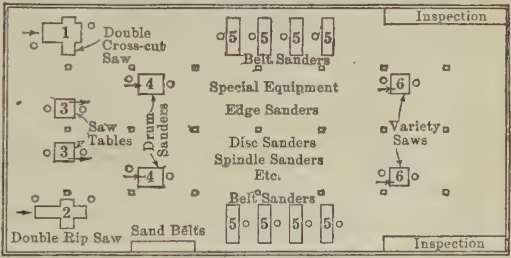

Fig. 39. Arrangement of Dimensioning and Sanding Department. O indicates position of operator. Numerals show sequence of operations

**Sanding.**—Plywood is sanded to remove the veneer tape and to prepare surfaces for filling, staining, and lacquering. Usual operations are: 1. Preliminary sanding of the back side of the plywood on a roll or endless belt sander, to clean it and remove most of the tape; other back sanding seldom is necessary; 2. Similar sanding on the face, taking care that high spots do not sand through; 3. Finish sanding on belt or stroke sanders, with very fine sandpaper. Some authorities advocate doing all sanding of plywood with highly-figured face on belt or stroke sanders, to prevent the waste of sanding-through by careful operation. Fig. 39 shows a typical arrangement of a dimensioning and sanding department.

**Re-dimensioning** sometimes is practiced when plywood is glued and sanded in multiples, as with small parts, where separate handling would greatly increase costs. See Fig. 30.

**Inspection.**—The chief inspector usually is stationed between the sanding and crating departments, with sub-inspectors only in the face veneer and lumber core departments.

## Finishing

**FINISHING.**—The term *finishing* generally includes polish *sanding*, *filling*, *staining*, *lacquering*, *waxing*, etc. The preliminary sanding operations (see p. 22–22) precede the cabinet assembly stage. Final *polish sanding*, either by hand or by mechanical devices, after cabinet assembly, should leave a very smooth surface which will not place an undue burden on the filler. Many factories sponge before polish sanding to raise the grain, and cause the slender sander shreds to become more or less erect for removal in sanding. Since sponging tends to clean out the wood pores, they must be filled even with the surface, especially in open-grain woods like oak. The *filler*, silex and other ingredients, usually is a paste, diluted with naphtha. It is brushed on, allowed to dry partially, and rubbed into the pores with a circular motion. The surplus is wiped off, without removing any filler below the finished surface. Defective filling is indicated by pock-marks, when too much filler has been wiped off, or the depressions are too open for the filler to stick. Correct results should follow the first filling; deficiencies may be remedied by repeating the process. In modern finishing technique, filler replaces the many coats of varnish formerly used.

**Stain.**—After filling, stain is applied (this sequence is sometimes reversed), usually with a spray gun, to obtain the desired color. The color may be that to which the species will normally mellow from air exposure, or may be a purely artificial color. Stain and filler make end wood appear darker than side wood, because of the volume of penetration. Care must be taken to limit the amount of stain on colored areas. Stains are distinguished by the solvent as: 1. *Water stains*, erroneously called acid stains. They are the most permanent in color, but darken a trifle as the wood ages. They raise the grain more than other stains. 2. *Spirit stains*, dissolved in alcohol. They dry more quickly, fade easily, but do not raise the grain. 3. *Oil stains*, which are not extensively used in high grade furniture, because they " bleed " with the solvents used in later lacquer applications. In cheaper finishes, filler and stain are combined and applied in one operation; results are inferior. Water stain and aniline dyes, made from coal tar, are preferred for best all-around results.

**Varnish**, formerly a widely used final finish, has largely given place to lacquers, which have much shorter drying cycles.

**Lacquer.**—Many clear lacquers, of similar characteristics, gradually are developing into high-solid, quick-drying coatings. They perform more satisfactorily than varnish in drying ovens, and can be varied in constituents to meet the conditions of exacting service. A large number of them are made from a synthetic resin base, and many are formulated to withstand, without discoloration or blister, water, heat and alcoholic solutions. The number of coats applied varies, in general, with the degree of permanent finish desired. Consult the literature of the well-known makers of finishing materials for further details.

**Wax** is one of the oldest finishes known. It is applied as a paste over about two coats of shellac. The shellac is applied on properly stained wood, which then usually is sanded. After the wax is dry, it is rubbed to a dull polish. If rewaxed occasionally, an excellent and easily maintained finish is obtained.

**Other Finishing Materials** are *colored lacquers* and *enamels*, and various trade-marked products, some of which are of excellent quality. Their application is similar to the process outlined above. Usually a less expensive undercoater is applied, followed by the finish coats. Care must be taken to prevent the solvents used in the successive coats bleeding the preceding coats, thus producing muddy colors and sticky effects.

**ARRANGEMENT OF FINISHING EQUIPMENT.**—Fig. 40 shows a typical finishing department. Finishing rooms must be dust free, and thoroughly fireproof, since many solvent fumes are highly explosive. All fan motors must be spark proof. Conveyor chains and other moving parts should be guarded against friction and sparks. Fully air-conditioned finishing rooms permit standardization of drying conditions and make them independent of climate and weather.

Many finishing rooms have overhead conveyors, from which semi-finished units are suspended, progressing successively from station to station in the finishing cycle.

Some cheaper products are finished, in whole or in part, by dipping in tanks. Dipping applies especially to stains and sealers. Provision then must be made to drain and drip, to avoid excess material forming beads in objectionable locations.

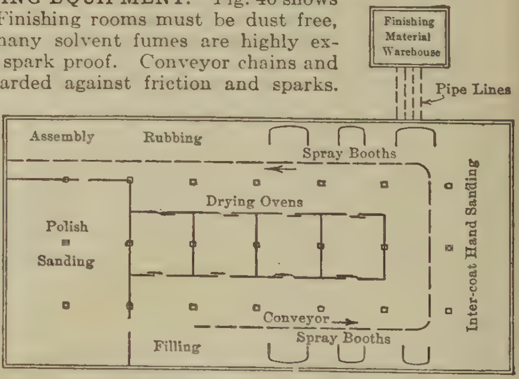

Fig. 40. Arrangement of Finishing Department.

**The Polish Sanding Department**, immediately preceding the application of finishing materials, should be separated from the spray booths by air-tight partitions to reduce dust hazards. Drying ovens should be centrally located, with several separately controlled, well-ventilated rooms to provide conditions required for drying filler, stain, undercoater and lacquer. Finishing materials are best stored in a separate fire-safe building, where all standard mixing can be done. All material should be piped and pumped to individual booth locations.

Hand sanding often is necessary between coats to remove small pimples that form around small particles of dust and undissolved solids. Many better grades of products require *rubbing*, to produce a dull, non-lustrous surface. On irregular shapes, rubbing may be by hand, or by holding the work against a cushioned revolving spindle. For table tops and similar products, mechanical stroke rubbers, with reciprocating cushion pads, are used. Rubbing down a good grade of lacquer gives a much better finish than semi-gloss lacquer, which lacks durability. The usual rubbing compounds are powdered pumice and oil, mineral oil and diatomaceous earth.

**Spray Booths** are almost universally used in finishing rooms. They are closely regulated by local ordinances, requiring direct fan connections to outdoors, to preserve health of operators and to reduce fire hazard. Spray booths generally are equipped with automatic revolving tables, with pneumatic vertical travel, to give access to legs, backs and under parts.

**Spray Guns** are atomizers, operated by compressed air at 75 to 100 lb. per sq. in. Guns giving smooth, glasslike, fan sprays are available that cover up to 60 in. width. Air volume may vary from $^1/_2$ to 50 cu. ft. per min. Dual, triple, and quadruple heads are available for attachment on spray guns for special products. Consult manufacturers' literature for details of spray booths and spray guns.

## Wood Preservation

Preservatives that lengthen the life of wood exposed to decay or attack by insects or marine borers are: 1. Preservatives of an oily nature, relatively insoluble in water; 2. Salts injected into wood in water solutions; 3. Toxic constituents in a volatile solution other than water; 4. Fire retardent wood treatments, which cover an industrial problem where municipal ordinances require fireproof construction. Intelligent selection for a particular service greatly prolongs usefulness of wood, with excellent ultimate economy.

**COAL TAR CREOSOTE,** the best known wood preservative, is a black or brownish oily distilate of coal tar. It is the most generally adaptable preservative for a wide variety of uses. The broadest field is outdoor service, with weather and underwater exposure. Its advantages are: 1. Toxicity to wood-destroying fungi and insects; 2. Relative insolubility in water and low volatility; 3. Ease of application; 4. Facility of determining depth of penetration; 5. General availability and relatively low cost. Its odor may be objectionable, but not serious, except where it may be transmitted to stored food products. The color sometimes is an objection where appearance is a factor, as creosoted wood cannot be successfully painted. Creosote does not increase the fire resistance of wood, but adds to its inflammability when freshly impregnated. The quality of coal tar creosote varies over a wide range. Grade 1 specifications of the A.W.P.A. (which are the same as those of the A.R.E.A.) should apply to creosote used for pressure treatments. For non-pressure treatments, the corresponding specifications of the A.W.P.A. should be designated. Coal tar, used alone, is too viscous for adequate penetration, but is used to dilute creosote for treating crossties. The blends most commonly used contain 20% to 30% tar.

**Creosote Petroleum** blends are extensively used for the treatment of crossties. On the average, blends contain 50% petroleum and although this decreases toxicity, it still is sufficient for the purpose. The presence of petroleum is claimed to retard checking, splitting and brooming. Creosotes of distinctly lower value for wood preservation are made from distillates of water gas tar and wood tar.

**Toxicity Tests** of wood preservatives may be defined as a " measure of extent or degree a substance acts deleteriously on wood-destroying fungi " (Schmitz).

**ZINC CHLORIDE** is a water soluble salt. Its chief advantages are: 1. General availability; 2. Relative cheapness; 3. Uniform quality; 4. Cleanliness; 5. Paintability; 6. Freedom from odor; 7. Ease of shipment; 8. Absence of fire hazard. On the other hand, it leaches out rapidly in damp soil and underwater locations, and is not as effective against decay as creosote. It is used in building construction, on roof planking, and is more adaptable for use on sawn lumber, as contrasted with creosote, on piles, posts, ties and large timbers. The preferable degree of impregnation is about 1 lb. of dry salt per cubic foot of wood, applied in 3% to 5% solutions, with subsequent evaporation of water solvent down to the moisture content required for the purpose intended.

**SODIUM FLUORIDE** is less soluble in water than zinc chloride, and leaches out of wood rather rapidly. It is approximately as effective as zinc chloride, but more expensive.

**MERCURIC CHLORIDE** has higher toxicity characteristics than zinc chloride. It is considerably more costly, and is objectionable because of its extremely poisonous character and tendency to corrosion.

**ARSENICAL PRESERVATIVES,** principally $As_2O_3$, have been used from time to time, but with questionable effectiveness.

The foregoing preservatives are no longer protected by patents. Some patented proprietary preservatives, among which are the three following, give excellent results.

**WOLMAN SALTS** are said to contain sodium fluoride as the principal ingredient in a water solution. They are of German origin, but have been used with reasonable success in the U.S. for mine timbers, roof timbers and miscellaneous lumber.

**ZINC-META-ARSENITE** is a somewhat recent American development. It is a water-soluble preservative. Experience with it so far has been encouraging.

**VOLTATILE SOLVENT SOLUTIONS,** in general, consist of a solution of beta naphthol, one of the chlor-phenols, or some other similar toxin in the light petroleum fraction commonly known as mineral spirits. These preservaties are clean, odorless and paintable, and when contrasted with water soluble salts, have the advantage of drying quickly. They are usable for treating window sash, doors, flooring, and other mill work. When properly applied, warping, twisting or raising of the grain is avoided.

**FIRE-RETARDANT TREATMENTS** are preferably by impregnation. They delay ignition and check the spread of fire over surfaces. For a thorough impregnation and a high degree of effectiveness, some authorities advocate approximately 300 lb. of chemicals per 1000 board feet of lumber, the cost of which often is prohibitive. Saturation must be as complete as possible, as many wood parts are extensively manufactured after treatment. Some fire-retardant treatments make the wood difficult to machine, requiring special cutters, frequently sharpened. Wood strength is not materially affected by fire-retardant treatments. The more usual chemical compounds for fire retarding have a predominating proportion of ammonium salts, but are rather complex and reference should be had to the literature of the industry and to that issued by the U. S. Bureau of Standards.

**EQUIPMENT AND PROCEDURE.**—All bark must be peeled from round poles and piles, to facilitate impregnation. Round pieces and sawn lumber must be well seasoned (air or mechanical), as any preservative treatment is practically useless when applied to green or wet wood. Sometimes this pre-drying is the initial step in the wood preservation process.

Complete impregnation is not essential, but penetration should be sufficiently deep to avoid subsequent checking or splitting exposing untreated areas. If possible, all cutting, framing, boring, etc., should be done before treatment. If such work is necessary after treatment, the freshly cut surfaces should be given two or three brush coats with hot preservative. Holes drilled on the job may be pressure treated by a simple device marketed for this purpose.

An approved method of increasing penetration depth and diffusion is *incising*. Sawed or hewed timbers are passed through a machine, in which teeth on horizontal and vertical rollers sink into the wood from $^1/_2$ to $^3/_4$ in. The incisions are closer on the denser and less absorptive woods.

**The Pressure Processes** are the most effective methods of treatment. The timber, separated to expose all surfaces, is placed on steel car bunks and run into a long steel cylinder, which then is closed and filled with preservative under pressure. Temperatures for efficient penetration usually are specified between 160° and 200° F., but are more advantageous toward the upper limits.

**The Full-cell Pressure Process** (Bethell) is preferable for both oil and water solutions, when retention of a maximum amount of preservative is desired. It is not so satisfactory when limited oil absorptions are specified. Limited absorptions of water-soluble preservatives are obtained by lower concentration of solids, and subsequent evaporation of the water. The steps in this process are: 1. Charging the cylinder; 2. Applying a preliminary vacuum (10 to 12 in.) to remove all possible air from the cylinder and wood pores; 3. Admission of hot preservative, without air, to the cylinder; 4. Application of pressure (150 to 175 lb. per sq. in.) until required absorption is obtained; 5. Withdrawal of preservative; 6. A short final vacuum to free the charge from dripping preservative.

**Empty Cell Pressure Processes** omit the initial vacuum step. In the Rueping process, an initial air pressure (25 to 100 lb. per sq. in.) is applied for a maximum of one-half hour with the denser timbers. The preservative is under a pressure of 150 to 200 lb. per sq. in. The Lowry process admits preservative to the cylinder under a pressure of 150 to 175 lb. per sq. in. without either initial vacuum or air pressure. Neither empty-cell process will impregnate as heavily as the full-cell process, due to the resistance of the air imprisoned in the wood cells.

**PRE-CONDITIONING.**—When natural or mechanical seasoning is impracticable, green timber is pre-conditioned, after peeling, on the treating car bunks in a closed cylinder, which may be the regular treating cylinder. The process most used for yellow pine is to steam the charge at 20 lb. per sq. in. (259° F.) for several hours, followed by a like period of vacuum. The effect of the vacuum is to lower the boiling temperature in the

**Table 14.—Specifications for Wood Preservation Treatments**

NOTE 1.—Empty-cell treatment recommended for ordinary conditions of use; full-cell treatment for exceptional conditions.

NOTE 2.—Not recommended for arid or very wet regions.

NOTE 3.—Full-cell treatment recommended for important permanent structures where long life is of special importance, or for use in warm, humid regions.

NOTE 4.—For North Atlantic waters.

NOTE 5.—For waters where marine-borer attack is severe.

NOTE 6.—For all waters where marine borers are active.

NOTE 7.—For use in the U. S.

NOTE 8.—For use in tropical regions.

NOTE 9.—Round posts recommended.

NOTE 10.—Full-cell treatment recommended for timber used under salt water. Empty-cell treatment suitable for most ordinary purposes.

NOTE 11.—For building lumber not in contact with ground, where painting is desirable, or creosoted material is otherwise unsuitable.

cylinder and facilitate evaporation of moisture from the wood. The Boulton process is a preferred, and less harsh treatment for Douglas fir and hardwoods. This is a boiling-under-vacuum treatment in which the standard cylinder charge is heated in the preservative oil at 180° to 210° F. under vacuum. As compared with steaming, the lower temperatures are less likely to injure the wood. The Boulton process removes more moisture from the outer surfaces (1 to 2 in. deep), but makes little change in the original moisture content below this depth.

**ABSORPTION AND PENETRATION.**—The absorptive capacity of wood varies considerably with different densities of wood species, and the varying cell capacities of sap and heart wood, and spring and summer wood. The amount absorbed is less per cubic foot in large timbers than in small poles, because of the larger proportion of center wood that is a negligible absorbing factor. A summary of Federal specifications for preservative treatment of wood is given in Table 14.

**NON-PRESSURE PROCESSES** do not impregnate as thoroughly as the pressure processes, but are the only practical methods for butt ends of poles, posts and other items that require treatment only on the sub-soil end. They sometimes are used on submerged wood, where low costs are imperative or when pressure tanks are not available.

**The Hot and Cold Bath Treatment** (Hunt process) is the most effective non-pressure process. The wood is heated in the preservative in an open tank for several hours, and then cooled in preservative for a like period. This may be accomplished by: 1. Transferring the wood from a tank of hot oil to one of cold oil; 2. Draining the hot preservative from a single tank, and quickly refilling with cold oil; 3. Shutting off the heat, allowing preservative and wood to cool together gradually.

Coal-tar creosote is the medium generally used in this process, as it is preferred for under-soil exposures. The hot temperature is about 230° F.; cooling should be to about 100° F. Higher temperatures penetrate better, but are subject to evaporative losses. The length of bath depends on the absorptive characteristics of the wood and the degree of penetration required. It is best determined by the conditions on each job. If penetration is insufficient, lengthen the time; if too much oil is absorbed, shorten the cold bath.

**The Steeping Process** is old, but not extensively used. Timbers are soaked in a cold solution of preservative for several days. It is mostly used with water-soluble compounds on sawn lumber, which should be separated to maintain complete face exposure. Only fair results can be expected, especially with treatments of 2 or 3 days duration. If time is not a factor, 10 to 15 days is much better.

**Miscellaneous Processes.**—In the *dipping* process, wood is submerged in preservative at 200 to 230° F. for 15 minutes. The effectiveness is limited. *Brushing* and *spraying* are even more superficial. Their use sometimes is unavoidable in emergencies, and on parts that have to be cut on the job.

## Wood Bending

Several processes of bending are in use. The technique differs between solid wood and plywood, as the fiber strain usually is much greater and more unbalanced in solid wood. Fundamentally, in bending wood strips the individual wood fibers tend to slide by each other slightly; outside fibers are stretched under tension, and inside fibers are compressed.

**WET BENDING IN SOLID WOOD.**—Any wood part is more easily bent when soaked or steamed to a point of thorough saturation. Consequently, bending is better and breakage less with steamed or cooked semi-dried lumber than with kiln-dried lumber, which is brash. Pieces to be bent should be dressed as nearly as possible to final sizes before bending.

The following process is applicable to pieces of approximately square cross-section; for wider or flat pieces, see Dry Bending below. Three factors are important in wet bending: 1. A smooth rigid form without abrupt changes in curvature on the concave side of the curve; 2. A thin flexible metal strip, on the convex side, drawn tight, to reduce breakage; 3. Sufficient end pressure to eliminate danger of shear on any fiber line. See Fig. 41. The cycle of bending and drying is much shortened if forming is done in a press under heat.

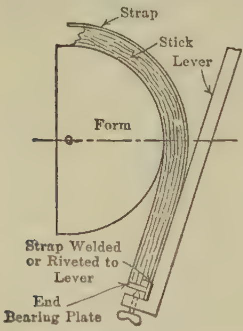

FIG. 41. Fixture for Wet Bending

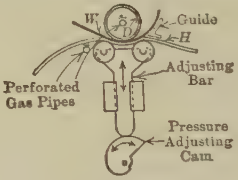

FIG. 42. Arrangement for Dry Bending Solid Wood

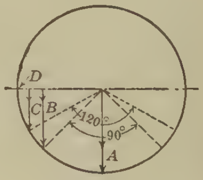

FIG. 43

**DRY BENDING IN SOLID WOOD.**—A preferable method of bending wider and thinner pieces of solid wood is a series of three rollers, as in Fig. 42. Heat is applied to the upper roller *D*, and below the endless steel flexible conveyor belt *H*. The wood *W* is rocked back and forth until the desired degree of curvature is obtained. Temperatures may be as high as possible without charring wood surfaces. This method can be used for such items as curved slats for chair backs, and for plywood up to $^5/_{16}$ in. thick, if the adhesive is heat resistant (resin or casein). The bent pieces, both of solid wood or plywood, should be placed in skeleton curved forms until thoroughly cooled and normalized as to moisture content.

**BENDING PLYWOOD DURING GLUING ASSEMBLY.**—As a practical manufacturing problem, only such curves can be economically bent in plywood assembly operations as can be formed in hydraulic presses with vertical pressure. There is a definite limit to the extent of curved segments that can be glued effectively. Fig. 43 shows that, with a given direct pressure *A*, a 90-deg. segment will have a pressure of approximately $^2/_3$ *A* at its extremity *B*, while a 120-deg. segment will have a pressure of $^1/_2$ *A* at the extremity *C*. It is possible to bend a 120-deg. segment successfully, and it will include enough more than a quadrant to produce grooved and well-fitted corners. A 180-deg. segment would have no vertical pressure component at *D*; pressure would be derived only from the snugness of the forms. The limit of 120-deg. segmental angle applies to both simple and compound curved surfaces.

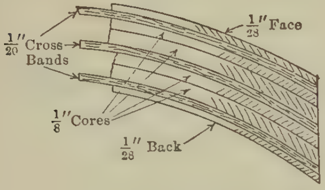

FIG. 44. Typical Curved Construction, Thick Plywood

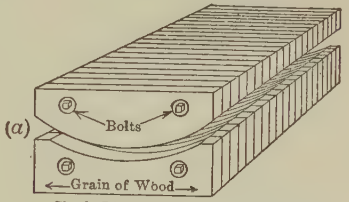

Single Wood Forms for Cold Pressing
(For Hot Pressing made integral of Aluminum)

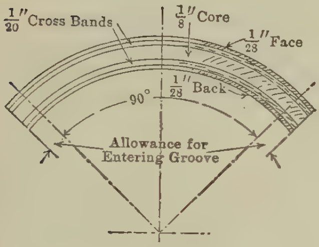

FIG. 45. Typical Curved Construction, Thin Plywood

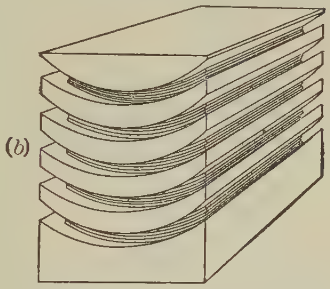

Multiple Aluminum Forms for Cold Pressing

FIG. 46. Platens for Bending Plywood

Figs. 44 and 45 show typical curved segment plywood constructions. The thickest layers of veneer are bent with the grain, and thin sheets only are bent against the grain. Increasing the number of plies (Fig. 44) often facilitates the bending operation, and reduces the thickness of the layers.

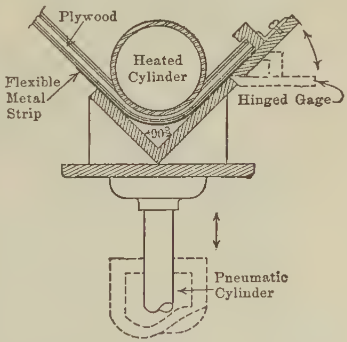

FIG. 47. Plywood Bending Press

**Cold Bending.**—Plywood bending operations can be done with liquid adhesives, vegetable, casein and animal glues, in unheated hydraulic presses, utilizing the usual I-beam clamps on one or a series of pairs of forms (Fig. 46). A quick-setting (3 to 4 hr.) glue should be used to reduce investment in forms. After removal from gluing forms, the curved plywood should be racked in curved skeleton forms, and weighted during re-drying. See p. 22–26.

**Hot Bending.**—Better results are obtained by making curved plywood with film or liquid resin in a hot press. Single assemblies of plywood are bonded, in one pair of male and female forms similar to Fig. 46*a*, but made of aluminum. A pair of forms is placed between each pair of heated platens. Upon completion of bonding, requiring about 10 minutes, the forms are again available and may be used as many as 50 times per day. The plywood does not require re-drying to remove glue water, nor is curved hot-pressed plywood inclined to warp or lose shape.

**BENDING PLYWOOD AFTER BONDING.**—Plywood with water-proof resin bonding can be steamed and softened after bonding to facilitate bending. This has opened up a new technique for curved plywood, allowing sharper bends and curvatures up to nearly a complete circle. These bends can be made in 1/8-in. plywood and thinner without recessing or cutting away on the concave side. Plywood thicker than 1/8 in. and up to approximately 1/2 in. is recessed on the concave side, leaving about 3/32 in. of plywood in the bend. The plywood is thoroughly steamed at the point to be bent, placed in a bending press, Fig. 47, and the lower female form pressed up against a heated cylinder of the required diameter. The effect of the heat is to set the bend permanently. If the resulting bend is to be framed in a groove no reinforcement is necessary (Fig. 48*a*). If the curved plywood is unsupported, a sheet of veneer should be added (Fig. 48*b*), with its grain running around the curve, and bonded to the inside curve by a liquid or film resin. This latter construction is patented.

The process of bending plywood with lumber cores is somewhat different. The back is recessed, as in Fig. 49*a*, down to the face crossband, leaving only the crossing and face to be flexed. The wood core is cut to such a miter as will meet when the curve is made. A sufficient slot is provided, next to the face crossband, into which a glue-covered spline can be inserted, the grain of the spline being parallel to the axis of the curve. When the glue is set on the curved spline, the joint will be firm. Glue setting usually is done while the plywood is clamped in curved position.

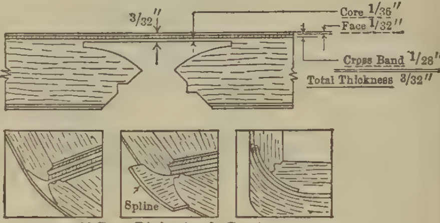
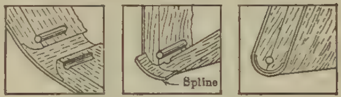
FIG. 48. Bending Plywood After Bonding



*a.* 90-Deg. Right Angle Bend



*b.* Full 180-Deg. Bend

FIG. 49. Bending Plywood with Lumber Cores

**FLEXIBLE PLYWOOD** may be made 3-ply with a very thin core, and thick loosely-cut outsides. It is suitable only for rougher uses that are to be painted, and is not adaptable to figured face woods.

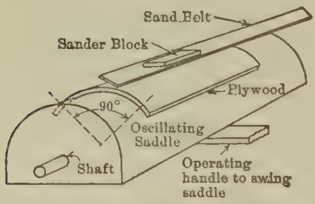


FIG. 50. Method of Sanding Convex Plywood

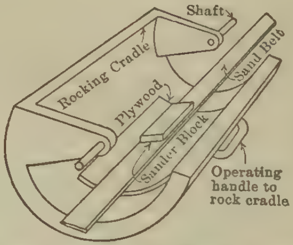

FIG. 51. Method of Sanding Concave Plywood

**SANDING OF CURVED SHAPES** presents some unusual problems. Good results may be obtained by attaching either the saddle or cradle, Figs. 50 and 51, to a belt sander to facilitate sanding either the inside or outside face of curved plywood.

## 4. SMALL TOOLS

Small tools for woodworking can, in general, be used practically unchanged for working the plastic and phenolic materials, and also rubber.

**THEORY OF CUTTING WOOD.**—Wood is made up of parallel fibers. Cutting lengthwise is simply peeling a layer of fibers off from those below, as with a splitting axe or carpenter's plane. In cutting across the fibers, every fiber must be severed. A knife or chisel driven forcibly across grain is the simplest form of cross cutting. Both examples represent " line " cutting without waste.

Saws divide the fibers, lengthwise or crosswise, by cutting out a swath or *kerf*. In a cross-cut kerf the fiber first is severed at both sides of the swath; the short cut fiber then is removed by a lengthwise cutting at the bottom of the kerf. In ripping a kerf with the grain, the fiber in the swath to be removed first is cross cut and then peeled loose from the sides of the kerf. Cross cutting requires a knife point cut at each side of the kerf. This is made by teeth alternately high at the sides and pointed and beveled on the front. *Raker* teeth may be used to peel or split the severed fiber and remove it. Ripping requires chisel-pointed teeth, set or swaged to the width of the kerf, and with enough hook to sever the fiber with an adzing cut. It simultaneously is split loose at both sides and removed.

Saws are set, or hollow ground, to reduce friction. Surface tension or case-hardening of the lumber may cause boards to pinch or close the kerf during a cut. This is one of the principal reasons for wide clearance and wide kerfs. See Fig. 52*d*.

With revolving *cutter heads* having knives or bits, the cut generally is lengthwise. It is not exactly a splitting cut, since only at the finish line of straight grain woods is the cut parallel with the grain. At other parts of the cut, the knives are chiseling or adzing, and cross-cutting the grain.

**SAWS** may be classified generally as: 1. Saws for the *primary conversion* of logs into lumber and timber. Being used on live or green logs, there is no danger of overheating and damaging saw temper. Such saws should be designed to cut smooth and to close dimensions, as subsequent shrinkage necessitates machining to final size and shape. Cutting of tough, green wood requires a different tooth than does the cutting of stiffer and stronger, but more brittle, dry wood. 2. Saws for the *secondary conversion* of the board after seasoning, into intermediate or final products. Saws may overheat and lose temper in dry wood, and may scorch or discolor it. Accurate, smooth cuts must be made, to produce final dimensions with maximum smoothness and minimum waste. Tooth shape must be such as will cut rapidly without heating, and accurately, with minimum power requirements. The thickness of saws is designated by Stubs gage. See p. 6–23.

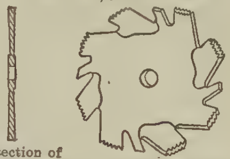
*b.* Circular Cut-off Saw

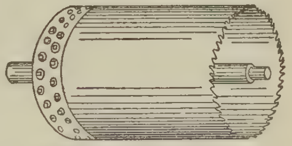
*c.* Combination Saw. Ripping teeth with short rake, and cross-cut teeth



*d.* Cross-section of combination saw hollow ground
*e.* Huther Patent-tooth Solid-plate Grooving Saw

*f.* Band-saw Teeth Showing Hook

*g.* Narrow Band-saw Teeth



*h.* Cylinder Saw for Barrel Staves

FIG. 52. Forms of Saw Teeth

These two general classifications may be still further subdivided as below. Fig. 52 shows the various forms of saw teeth.

Saws for primary production (converting green logs into timber and lumber):
- Circular saws
  - Solid discs
    - Parallel-to-grain or rip cut (Fig. 52*a*)
    - Perpendicular-to-grain or cross cut (Fig. 52*b*)
  - Inserted teeth
  - Shingle saws, thin edges with thick centers
- Band saws, continuous or endless (Fig. 52*f*)
  - Parallel-to-grain for cutting logs into lumber and timber
  - Perpendicular-to-grain, drag saws for log lengths
- Band saws, reciprocating, mostly gang resaws
- Special purpose saws
  - Cylindrical, for cooperage stock (Fig. 52*h*)
  - Concave

Saws for secondary production (converting dry boards into diversified wood products):
- Circular saws
  - Ripping (Fig. 52*a*)
  - Cross cutting (Fig. 52*b*)
  - Combination (Fig. 52*c*)
  - Special purpose (Fig. 52*e*)
- Band saws, continuous or endless
  - Ripping or resawing, wide (Fig. 52*f*)
  - Curved and special shape, narrow (Fig. 52*g*)
- Band saws, reciprocating
  - Jig and scroll saws
- Special purpose saws
  - Dadoing (Fig. 52*e*)
  - Tennoning and mortising

**KNIVES AND CUTTERS.**—The function of a knife or cutter on a planer, moulder or shaper is to reduce the surface or edge of a part to the desired shape and dimensions without marks or scratches, and with a smoothness that can be finished. A roughly-sawed surface or edge requires more subsequent machining than one smoothly sawed. Close correlation between the roughness of the saw cut and the depth of the planer cut is necessary. Often, as in jointing plywood cores, a saw can be made to cut smooth enough to eliminate a separate jointing operation. A slightly rough cut is considered better for gluing than one with too smooth an edge.

The basic machines using knives and cutters are: 1. Planers or jointers using straight cutting edges to produce plane or level surfaces. They cut continuously along a straight face, not on the side, and parallel or nearly parallel to the grain. 2. Moulders or stickers, which are, in effect, multiple planers, usually designed to cut straight or irregular surfaces on all four sides of a piece simultaneously. Cutting may be with either face or side of the knife, but substantially parallel with the grain. 3. Shapers, which are particularly designed to produce irregular and curved shapes or edges both in vertical and horizontal planes. They use a variety of solid, sectional, and laminated cutters, often cutting at an abrupt angle to the grain.

On relatively large diameter wheels, the method of attachment of knives and cutters for planers, moulders and shapers, determines the classification. This involves both the provision made for knife attachment, and the corresponding design of head to which knives are attached. Rigid mounting is imperative because of high operating speeds, strong centrifugal forces, and the deep cuts often required.

Knives are distinguished, in general, by thickness as: 1. *Thick knives*, usually comprising a tempered steel face and cutting edge, welded to a softer steel back used for clamping. Narrow knives of the chisel type may be entirely of tool-steel, tempered principally at the cutting edge. 2. *Thin knives* which require clamp bars and plates, or attachments. Such tool-steel knives seldom are recessed for attachment. They require stiffer bars to provide rigidity and firmness. A knife that chatters will not cut smoothly.

Knives and cutters may be classified by machines and by thickness, as follows:

**Planers and Jointers** for cutting straight surfaces, single and double, parallel to wood grain.
- *Thick rigid knives*, parallel to axis of head (Fig. 53*a*)
  - Square heads
    - Two-knife (Fig. 54*a*)
    - Four-knife (Fig. 54*c*)
  - Face clamping
    - Oval holes in knife with bolts adjustable in slotted head (Figs. 53*b*, 54*c*)
    - Slotted holes in knife, with tapped holes in head (Figs. 53*a*, 54*a*)
    - Ribbed-surface knives for rigid clamping (Fig. 53*c*)
  - Round heads
    - Clamped with countersunk bolt heads
    - Internal bolt clamping devices
- *Thin knives*, semi-flexible, requiring support and clamp bars (Fig. 53*d*)
  - Knives parallel to axis of head
    - External clamp bars and bolts
      - Square heads (Fig. 54*d*)
      - Round heads (Fig. 54*g*)
    - Internal clamp bars and bolts (Figs. 54*e*)
    - Wedge and taper clamps (Fig. 54*f*)
  - Knives spiral to axis of head
    - External clamp bars and bolts
    - Internal clamp bars and bolts

**Moulders and stickers** for cutting multiple straight and irregular surfaces parallel to wood grain (Figs. 56*a*, 56*b*, 56*c*)
- *Thick rigid knives* (straight, not spiral)
  - Angular heads
    - Two-knife (Fig. 54*a*)
    - Three-knife (Fig. 54*b*)
    - Four-knife (Fig. 54*c*)
  - Face clamping
    - Tapped holes in head (Fig. 54*a*)
    - Bolt slots in head (Figs. 54*b*, 54*c*)
    - Ribbed-surface knives for rigid clamping (Fig. 53*c*)
  - Edge clamping
    - External bolts (Figs. 55*a*, 55*b*)
    - Vise or jaw clamps (Figs. 55*c*, 55*d*)
    - Slotted bolts with adjustable cutting angles (Fig. 55*c*)
  - Round heads
    - Clamped with countersunk bolt heads
    - Internal bolt clamping device
    - Wedge and taper clamps (Fig. 55*f*)
- *Thin knives*, semi-flexible; requiring support and clamp bars
  - Knives, parallel to axis of head
    - External clamp plates and bolts (Fig. 54*d*)
    - Internal clamp plates and bolts (Fig. 54*e*)
    - Wedge and taper clamps (Fig. 54*f*)
  - Knives spiral to axis of head
    - External clamp plates and bolts
    - Internal clamp plates and bolts

**Shapers** for cutting irregular surfaces in two planes and frequently at abrupt angle to wood grain
- *Knife blades clamped to head*
  - Face clamped to head
    - Slotted hole, tapped hole in head (Fig. 54*a*)
    - Slotted knife and bolt in head (Figs. 54*b*, 54*c*)
  - Edge clamped
    - External bolts (Figs. 55*a*, 55*b*)
    - Vise or jaw clamps (Figs. 55*d*, 55*e*)
    - Slotted bolts with adjustable cutting angles (Fig. 55*c*)
  - Clamped with pressure bars or plates (thin knives)
    - External clamped with countersunk bolt heads
    - Internal clamped
    - Wedge and taper clamps
  - Thin knives of slightly irregular shapes (Figs. 56*a*, 56*b*, 56*c*)
- *Solid knife heads mounted on arbor*
  - Thick knives of a wide range of shapes (Figs. 56*d*, 56*e*)

**BORING TOOLS.**—The principle underlying a boring tool or bit is similar to that of a shaper tool, except that the boring tool advances into the wood. Mechanical means must be provided for this movement, as well as for the removal of chips from the enclosing hole along the spiral shank of the bit. The two basic types of boring tools are: 1. Boring into *side wood,* where the bit requires side spurs to sever the wood fibers on the circumference of the hole, before the cutting and lifting edge of the bit separates the chips along the fiber line. 2. Boring into *end wood,* where the bit shears off the fibers as it advances, the cutting of the circumference being merely a separation of the fibers. See Fig. 57.

**Bits.**—Fig. 58 shows four main types of bits. The *double-spur* bit is a general utility tool, usually made with a single-thread screw point. The *extension lip* bit usually has a double-thread point. It is used to produce smoother holes, with less liability to split hard

*d.* Thin Solid Knife Head *e.* Thick Solid Knife Head

FIG. 56. Bits and Solid Knife Heads

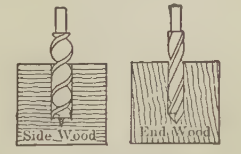

FIG. 57. Boring into Side and End Wood

wood. Both types are used to bore holes in side wood. The *taper head drill* is designed for boring end wood. It may be used for side wood if a rough hole is not objectionable. The *spur machine drill* is a modification of the taper head drill. It has spurs and a brad point, to adapt it to better boring service in side wood. It is used in gang boring where holes may be at various angles to the grain.

The kind of spiral groove or twist for chip removal, depends on bit size, depth of hole, and direction of grain. Fig. 59 shows the more important types. The *double twists* are usual for medium and large regular boring; left-hand is standard for a bit turning clockwise. Some gang boring machines require right-hand twist bits, rotating counter-clockwise. The *solid center twist,* with a round stem or shank in the center, is used for small bits. The *ship auger twist* has the largest body of metal on the edges, the center being used for more adequate chip removal. It is most suitable for deep boring in large timbers. The *drill twist* has a much more rapidly rising spiral than others, its function being the removal of smaller end wood cuttings, rather than side wood chips. It is so ground that the margin is wide enough to resist wear, thus maintaining the diameter.

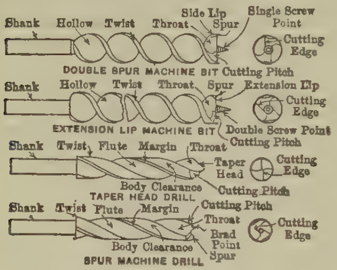

FIG. 58. Types of Boring Bits

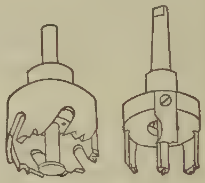

FIG. 62. Plug Cutter

*a.* Single-flute Router Bit

*b.* Double-end Router Bit

*c.* Double-flute Router Bit Made Right and Left Hand

FIG. 63. Router Bits

Fig. 60 shows bits for boring concentric holes, sometimes called counterbores. The countersink *a* is for flat-head screws, while recessing, as for washers or bolt heads, is done with one of the forms of counterbore of which *b* and *c* are examples. Many other combinations may be made for both side and end wood.

Large diameter shallow holes do not require bits with spiral shanks, as chips seldom clog. Fig. 61 shows two types, *a* for solid wood, and *b*, with saw teeth on the circumference, for plywood. Both have brad points.

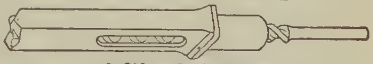
Fig. 62 shows *plug cutters* with ejector plungers, one of which has inserted high-speed steel teeth for abrasive plywood adhesives, as casein.

Router Bits, Fig. 63, while similar in appearance to boring tools, have different functions. A router is chiefly used to cut recessed grooves, or to cut out, by means of grooves, regular or irregular outlines. A router bit has a cutting lip throughout its length to produce smooth-edge grooves. It rotates at much greater speeds than a boring bit. The function of side cutting is much more important than end cutting. The advance cut of a spur is not needed, and the fluted clearance slot, for chip removal, may be straight instead of spiral. Router bits may be designed for various shapes, like T-slots, ogee grooves and the like. In this form they may resemble shaper knives and heads.

**MORTISING TOOLS,** Fig. 64, are duplex boring and chisel cutting tools. A central standard bit bores a round hole, and, surrounding the bit, a square four-side chisel removes or broaches out the round fillet corners. Chips from both cuts are lifted out by the spiral shank of the bit and discharged through clearance clots in the square chisel shank (one for soft wood, two for hardwood). The slots are located above the wood surface at maximum cutting depth. Chisel points are longer at the corner than at the center, to insure a shearing cut in removing corner fillets.

Oblong holes, up to 1 $1/_2 \times 1$ dimension ratios, can be made with a rectangular oblong chisel, as in Fig. 64*b*. If a 2 × 1 ratio is required, and the shape of hole is concealed by shoulders on the tenon, the result can be obtained at a single stroke by the hollow chisel, Fig. 64*c*. The cutting edges of the chisel are arranged for shear cuts on all four sides. Otherwise, oblong holes are made by multiple strokes of a square mortising tool. Proper clearances must be provided between internal bits and external chisels to avoid friction, heating and burning the wood. In setting mortising tools, the chisel is set first, and then the bit, with the bit cutting lips extending a little beyond the extreme cutting tips of the chisel. Mortising tools are not suited for cutting end wood.

*a*. Hollow Chisel with Chisel Bit



*b*. Oblong Hollow Chisel

*c*. Oblong Bar Hollow Chisel

FIG. 64. Mortising Tools

**Mortising Chains** are available for oblong holes, being a series of cutters attached to an endless chain. They are not boring tools, but produce a similar result. The hole has a rough edge, but may be satisfactory for such products as mortise-and-tenon doors, although the joint cannot be very snug.

## 5. MACHINE TOOLS FOR WOOD *

### Saw Machines

The five principal types of saw machines are: 1. *Rip-saws*, circular cutting; 2. *Cross-cut saws*, circular cutting; 3. *Variety saw tables*, circular cutting; 4. *Band saws*, continuous band cutting; 5. *Jig* and *scroll saws*, reciprocating band cutting. In many machines, rip, cross-cut or combination-tooth saw discs may be used interchangeably, while some are single purpose machines. See p. 22–35 for saw disc types and teeth.

Saw cuts are required on a variety of machines, where the saw cut is auxiliary to the general purpose of the machine. Examples are double-end tenoners, dado heads or grooving cuts on moulders, trim cuts on veneer jointers, or a cut-off on a dowel machine. In general, the best cutting speed for either a circular saw or band saw is approximately 10,000 ft. per min.

**RIP SAWS.**—Machines designed exclusively for ripping are of two main classes: 1. Single or multiple ripping of full length boards, often the preliminary dimensioning operation in a planing mill, and sometimes in a furniture factory. In gang set-ups, to avoid a winding cut, saws must be of equal diameter and approximately the same degree of set and sharpness. Saws usually are mounted on the lower arbor, with pressure or feed rollers above. 2. Single ripping of cross-cut stock (often called straight-line rip saws). The saw usually is mounted above, with an endless feed chain below. Such saws often give a sufficiently straight and true edge for gluing. Arbors are sometimes below the work, the saws extending upward between a divided feed chain, above which are mounted idling pressure or feed rollers.

**CROSS-CUTTING SAWS** (also called stock-cutting saws) may be of the following types: 1. Swing saw (an older type) hung from the ceiling and swinging into the work on an arc; 2. Clip saw, swinging from below, with the motor drive pulley concentric with the pivot; 3. Saws on sliding ways, or other mechanical device, to move them horizontally into the work and out. Cross-cutting usually is the first dimensioning operation in a furniture factory.

**VARIETY SAW TABLES** may be equipped interchangeably with rip, cross-cut or combination (rip and cross-cut) saw discs, depending on the work. For grooving or tenoning, dado heads or *wobble saws* may be used. Wobble saws are angle mounted, with wedge-shaped collars, between two perpendicular saws for slotting or rabbeting. Variety saw tables generally are equipped with side gages, back gages, and angle adjustments for miter sawing. For angle cutting, the table may tilt or the arbor may be pivoted. In size, they range from small bench saws up to floor machines. Speed of floor units usually is 3400 to 3600 r.p.m., requiring 5 Hp.

---

* For machines for primary saw mill conversion operations, see p. 22–09.

Since all circular saws cut against the feed, the operator should take great care to avoid dangerous " kick backs." Most modern saws have mechanical devices to protect against both kick backs and hand hazards from the saw discs.

**BAND SAWS.**—Resaws for such operations as ripping special thicknesses, usually are about 6 in. wide, with heavy corrugated feed rollers on vertical shafts. Regular band saws may be equipped with a variety of blades, seldom wider than 1 in. for straight work, and down to $^1/_4$ in. for curved work. Band saw wheels range from 30 to 36 in. diameter, with direct-connected motor on the lower wheel. Band saw throats take work up to 36 in. wide by 18 in. thick. Motors are 3 to 7 $^1/_2$ Hp.; wheel speeds are 600 to 1200 r.p.m. Small bench models also are made.

**JIG AND SCROLL SAWS** are used chiefly for cut-outs that cannot be made on band saws, and are much less costly than band saws for small shops. The development of the high-speed router, producing smoother edges, has greatly lessened the utility of the jig saw.

## Planing Machines

The underlying principles of cutting wood surfaces in the planer also are used in the jointer, moulder (sticker) and flooring machine. The following explanation of these principles in the planer, applies also to these other types of machines. See p. 22–37 for the forms, shapes and methods of attachment of knives.

**CUTTING MECHANISM.**—Fig. 65 shows a section of a typical planer cutting mechanism. The cutting head revolves against the infeed of the stock, and the grooved *infeed rolls* should be powerful enough to withstand the double load of feeding stock and holding it against the action of the cutters. Infeed rolls often are made in sections to bear more uniformly on thick and thin stock. Large single surfacers and all double surfacers have two pairs of infeed rolls. Pressure of the feed rolls tends to straighten crooked lumber, and the ordinary planer cannot be relied upon to remove wind and warp entirely. A special type (straitoplane) is used for this purpose. See p. 22–42. The *chip-breaker* prevents lifting and tearing of the grain, and reduces all chips to a size that will not clog the cutting head, nor be difficult to move as shavings in the dust collector system. The steel tipped chip-breaker shoes ride the top surface of the incoming lumber, and are substantially concentric with the cutter head. They are suspended from a sturdy cross bar, as a heavy cut places a severe strain on chip-breaker mechanism. The smooth *outfeed roll* and the *pressure bar* require exact adjustment to the final planed thickness. They must be rigid enough to prevent any chatter or end clipping in the board during the planer cut.

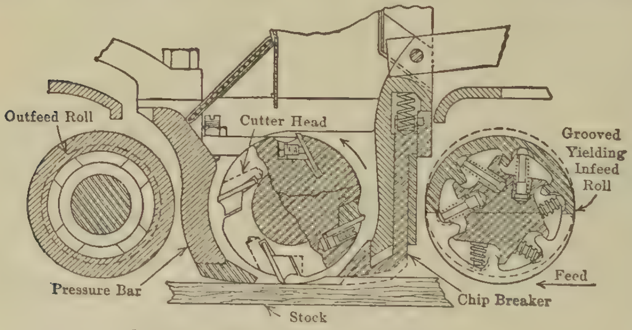


Fig. 65. Planer Cutting Mechanism.

The *cutter head* in Fig. 65 is of the round type with four thin knives, clamped in slots. While it is possible to set the several knives in approximate alignment, it is necessary to joint or grind all knives, at operating speed, to a true cutting line, after they have been set and clamped in the head. This preferably is done with a special motor-driven traveling grinder mounted over the main bearings of the planer. In some cases (as an enclosed lower knife head), the head is partially or wholly removed, with the knives clamped in place and ground in that position.

*Planer cutting circles* usually are about 6 in. diameter but vary with the different makers and shaft lengths. Since the standard speed of planer shafts usually is 3600 r.p.m. (7200 when a frequency changer is used), it is important that they be in perfect mechanical and static balance, requiring careful attention to the individual weights of knives and clamping devices. One of the most difficult problems of planer design is to overcome shaft whip or deflection at high speeds, especially in the wider machines, tending to produce uneven thicknesses and rough planing.

Proper *cutting angles* are important. They vary with the species and dryness of the wood. Table 15 gives their dimensions.

**Knife Cuts per Inch.**—A definite relation exists between the rate of feed, the peripheral speed of the cutter and the number of knives in the shaft. At best, any planer cut is a series of miniature waves in the planed surface, the degree of smoothness depending on the shortness of the individual waves. This relation is clearly indicated in Table 16.

**TYPES OF PLANERS.**—The principal types of planing machines are: 1. General-purpose planers; 2. Cabinet planers, for high quality work; 3. Mill-type planers, for surfacing full length boards.

**General-purpose Planers,** ordinarily used in so-called planing mills and job shops, have a bed (thickness) adjustment in vertical ways by means of two geared screws. With

**Table 15.—Cutting Angles and Knife Cuts per Inch for Planers and Similar Machines**

| Birch | 4–9 | 12–14 | 9–13 | 12–14 | 13–18 | 10–13 | 13–18 | 10–13 |
| Maple | 4–9 | 12–15 | 9–13 | 12–14 | 13–18 | 12–14 | 13–18 | 12–14 |

Above figures apply to stock 1/2 in. thick or thicker. For stock less than 1/2 in. thick, increase the knife cuts per inch 10–50%.

To prevent tearing out grain on dry stock, decrease the cutting angle or increase the knife cuts per inch.

To prevent roughing up or raising the grain on wet or green stock, increase the cutting angle and decrease the knife cuts per inch.

**Table 16.—Knife Cuts per Inch with 3500 R.p.m. Spindle Speed**

(R.p.m. × Number of Knives)/(Ft. per Min. × 12) = Cuts per inch

| Feed of Work, ft. per min. | Number of Knives per Head | | | | | | | | Feed of Work, ft. per min. | Number of Knives per Head | | | | |

this construction a slight rocking motion is unavoidable, when stock is entering the infeed or leaving the outfeed rolls, which may be unimportant in many rough planing operations that do not require precision. Since the average cost of this type is less than that of the cabinet planer, it usually lacks the better attachments and more accurate adjustments of the latter.

**Cabinet Planers** owe much of their precision to bed adjustment by motor-actuated sliding wedges, giving both accuracy and rigidity. The range of adjustment is less than that of the general purpose planers, but tendency to rock is entirely eliminated. In cabinet planer design, the point of the chip-breaker is placed as close as possible to the actual point of cutting, to reduce the size of chips, and lessen the tendency to tear out ahead of the cut. The chip-breaker usually is of sectional or flexible construction, to ride equally well on thick, thin and rough spots in the stock. High-grade planer work demands a large number of knife cuts per inch, which is obtainable either by increasing the number of knives (up to six, rarely more) in the head, or stepping up the speed of the shaft, a point on which opinion (1937) is divided. Straight knives generally are used, but spiral knives occasionally are used to distribute the load and reduce pull-outs at the back end of the stock.

**Motor Equipment** for planers varies with the service. Standard power ratings for single surface cabinet planers are:

| Planer width, in. | 26 | 30 | 36 | 40 | 44 | 50 | 60 | 64 |
|---|---|---|---|---|---|---|---|---|
| Horsepower | 10–15 | 15–20 | 20–25 | 20–25 | 20–25 | 20–25 | 25–30 | 25–30 |

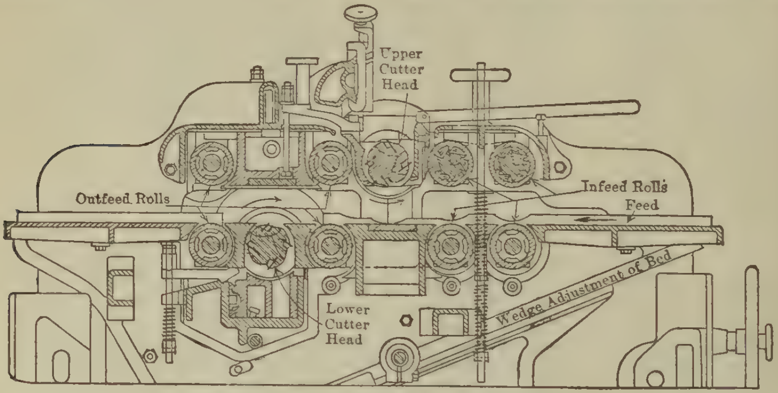

Fig. 66. Feed Mechanism of Cabinet Planer

**Feed Mechanism** may be driven direct from the motor on the cutter shaft by belt, often a severe handicap when using frequency changers, or by separate multiple-speed constant-torque motors. Speeds usually are up to 60 ft. per min., occasionally 100 ft. per min., with considerably slower speeds for exacting work.

Production cabinet planers often are fitted with *hopper feed*, the infeed bed or table being equipped with an endless rubber-faced conveyor chain, with slats or side rollers for random lengths. Hopper feeds usually are set on an angle to feed pieces diagonally.

Cabinet planers are made for double surfacing, the lower cutter shaft then being arranged to be pulled out for adjustment and jointing. See Fig. 66. Double surfacing planers usually are built from 30 to 44 in. wide with larger power requirements than single surfacers.

**The Straitoplane** is an unusual type of double surfacer in which the lower cut is made first. The freshly-cut under surface of the board then is advanced on to the rigid center bed, against which a second cut is made by the upper cutter head. During the first cut, the stock is held by an overhead flexible-fingered feed-chain, thus providing one true surface. The second cut can be adjusted for accurate thickness. This machine operates efficiently on stock as short as 10 in., and is particularly adapted to furniture work where most pieces are relatively small. Each cutter head is driven by a 15-Hp. motor at 3500 r.p.m. A 5-Hp., 2-speed motor drives the feed. The machine is standard at 36 in. wide. Feeds up to 60 ft. per min. are practicable.

**Mill Planers**, Fig. 67, primarily are designed for full-length lumber. They have been developed, and are principally used, on the Pacific Coast. Feed mechanism comprises endless chains with cross slats of ribbed cast iron, giving a more powerful and positive feed than is possible with rolls, but lacking somewhat in accuracy of cut. The cutter head is above, with the adjustments of a cabinet planer. Bed adjustment is of the sliding wedge type. Capacity is stock 8 in. thick, 30 to 36 in. wide. Feeds of 100 ft. per min. are practicable.

**JOINTERS** are classified as:

**Standard Jointers.**—The cutting mechanism of the jointer is quite similar to that of the planer, but the feed mechanism is omitted, since edged jointing is the predominant function of the jointer. Jointers are provided with a high *fence* (side gage) to permit them both to square and true the edge. Portable bench jointers are made and extensively used in preference to the hand plane. Jointers seldom are made over 16 in. wide, and sometimes are hand fed to take the wind out of dimension stock. This is particularly important in producing a true bed surface for moulder or sticker work.

**Lumber Jointer.**—The continuous feed lumber jointer has an automatic return feed for edge jointing strips for plywood core stock. This is a duplex or return cycle machine, with an endless feed-chain in the center, mounted on vertical shafts. The two cutter heads revolve in opposite directions. A board to be jointed on both edges is placed edgewise at the infeed end against the feed-chain, jointed on the lower edge, passed over a tipping mechanism that turns the unjointed edge down and into the reverse feed track. The board travels back to the infeed end, moved by the opposite side of the feed-chain, passing over the second cutter head. This machine is suitable only for use on ripped stock, as the cut is insufficient for rough or waney-edge stock, and it will not produce uniform width.

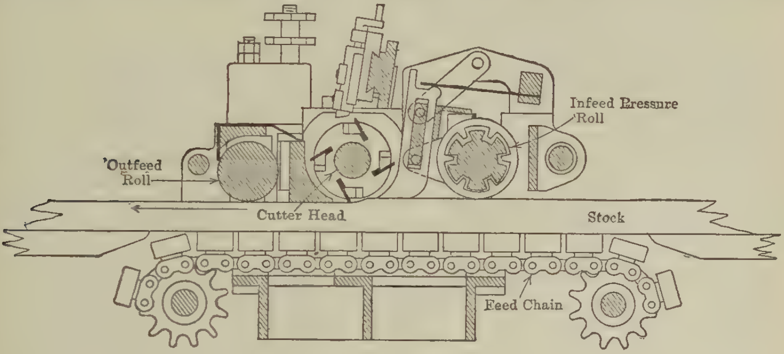

FIG. 67. Mill Planer

**Veneer Jointers** are highly specialized jointing machines. They operate on a flat *package* of sheets of veneer, aggregating 2 in. thick, which must be clamped firmly during the entire cutting period. The cutter head, usually mounted on a vertical shaft, carries as many as 12 knives to give the smooth edge necessary for matching high-grade veneer faces. In some machines the clamped package travels past the revolving knife head. In others, the clamp is stationary, and the head travels.

**MOULDERS OR STICKERS** essentially are four-sided planers, with two horizontal and two vertical shaft cutter heads, usually square 4-side heads (see Fig. 54*c*). The feed may be by pressure rolls against a rigid bed, or by endless feed-chain below. Cuts frequently made are irregular and curved faces on mouldings. Cutter heads so far as possible, have chip-breakers and the other auxiliary devices of the planer. Since all cutter shafts are short, knives and cutter heads are bolted on ends of shafts, and it is possible to use high speeds with frequency changers, up to 7200 r.p.m. Fewer knives are required at high speeds to give the same number of knife cuts per inch. This is a distinct advantage in grinding special knives as most moulder heads are 4-sided, and the uniform setting of 4 irregularly shaped knives is most difficult. It is usual to operate a moulder head at high speed with two opposed knives of the same shape and a correspondingly greater rate of feed. For long runs on standard shapes, solid cutter heads often are used, with knives jointed in a profiling machine.

Modern moulders have brackets for *cope heads*, which make re-entrant cuts that are not possible with regular heads. They also often supplement the regular heads by making deep cuts that would require impractical or very costly knives. Moulders are close coupled and compact, usually with individual motors for each head and for the feed. A popular size takes stock up to 4 × 4 in., but they are made up to 16 × 6 in. for heavy timbers.

**Flooring Machines** are specially designed moulders, the two vertical shafts making the tongue and groove, while the lower horizontal head makes the flooring face, and the upper head cuts the hollow back. A steel lettering wheel often grades and trademarks the back as it leaves the machine. Flooring machines are designed to operate on full-length lumber and at high speeds.

## Shaping Machines

**THE SHAPER** is one of the oldest types of machines. It still is important in woodworking, although many of its functions have been absorbed by more specialized machines. It is a versatile machine for small shops, as it is more easily set up for short runs than many of the specialized machines that are more efficient for long runs.

The shaper consists essentially of a large flat metal table with a vertical spindle, driven from below, extending up through the center of the table. Revolving cutter heads, mounted on the end of the spindle, accommodate a variety of knives for a wide range of cuts. (See Shaper Knives, p. 22–37.) Solid heads may be mounted for long runs. A job to which a shaper is best adapted is the shaping of the edges of table tops, especially those of other than rectangular form. The table top blank is firmly mounted, by two or more points, on a jig of the desired shape. A spindle collar is mounted at the machine table level, above which the knives are set and clamped for the required shape, ogee or otherwise. The operator revolves the combined jig and blank, holding it snug against the collar for one complete revolution of the jig, and thus producing the ogee edge around the periphery. Shaper knives cut with the grain rather than against it, as far as possible. Slow feeds are necessary when cutting at right angles to the grain. Blanks may be reversed on the jig to help this condition.

The shaper is especially useful in re-entrant curves, octagons and other odd contours not suited to machines designed for rectilinear or circular cutting. Small moulding, flutings, both straight and curved, and many edge and end cuts can be made on a shaper.

Shapers frequently are equipped with two spindles, usually rotating in opposite directions. All cuts around an irregular table top then can be made in a direction favorable to the grain, and no cuts have to " dig into the grain," leaving a rough and torn edge. The jig, with mounted work, is moved from spindle to spindle according to grain requirements. Automatic shapers are equipped with mechanically-operated jigs or revolving tables to which blanks are held with pneumatic clamps. These are suited only to long production runs.

## Routers

**THE ROUTER** is a relatively modern machine, achieving its effectiveness with the development of high spindle speeds. It is somewhat the reverse of the shaper, and usually is designed for considerably lighter cuts. The cutting head is above the table, which is provided with an upwardly projecting, jig-guiding round plug of the same diameter as, and directly under, the cutter. The cutter head carries a router bit (see p. 22–38) rotating at speeds of 20,000 r.p.m. or higher. The table may be moved up to the bit, or the bit lowered into the work. The router is admirably adapted to cutting out (with grooved cuts) grills or irregular shapes. It works much better and more quickly than jig saws. Router bits may have shoulders for shaping the edges of cut-outs, or T-heads for slotting. Straight cuts on narrow strips can be made by clamping suitable gages to the table. A straight gage, through or near the bit center, permits shaping of straight-edge table tops and similar work. Double-spindle routers are available with separate tables, facilitating work requiring two types or sizes of grooves on the same job.

Router motors, both electric and pneumatic, must be very accurately balanced for excessively high speeds. Brakes are provided to slow down the bits, which otherwise would require a long time to come to rest. Blowers, directed to the exact point of cut, are standard equipment to prevent chips and shaving from clogging the cut and heating the bits. Some routers are equipped with tilting tables. In these the bit is lowered into the work. Motors are 1 to 5 Hp. for heavy duty. Spindle speeds often are stepped up by V-belts.

**Portable Hand Routers** are built to operate electrically and pneumatically. Electric machines operate at 10,000 r.p.m. maximum; pneumatic, at 60,000 r.p.m. maximum.

## Carving Machines

**CARVING MACHINES** are of two main types, single and multiple.

**Single Carvers** may be rigidly mounted on a floor standard, the work being moved free-hand by the operator. The single carver also is available in the balanced suspension type, hung much like a dentist's drill. The work is held stationary and the drill moved over the pattern by the operator. In both types the mechanism consists of a small high-speed motor with a small spur drill mounted directly on the motor shaft. Single carvers are used for a certain amount of undercutting. Final retouching usually is by hand.

**Multiple Carvers** may carry as many as 24 blanks, all to be roughed out uniformly from a master pattern or model, usually of metal. The spur cutters are moved in unison by link levers that are fixed in their relation to each other. Cutters usually are belt-driven from one or more motors. Individual motors can be used for extra heavy cuts. Such machines can only rough out the carvings, but their efficiency consists in removing all surplus wood, even on deeply recessed carvings, leaving a minimum of hand carving of finer lines and under cuts. This type of machine has greatly extended the use of carving on classical furniture at very reasonable cost. But one operator is required, who guides the blank cutter over the pattern, carefully watching the direction of the cut to avoid tearing the wood. The hand finishing work reproduces the character of hand carving. This process is displacing pressed and overlaid imitation carved work.

## Boring Machines

**BORING MACHINES** range over a wide variety of woodworking machines, from a single bit held in clutch jaws on the end of a motor shaft, to gang or multiple machines in various arrangements, sometimes equipped for as many as 30 bits. Some bore only vertical holes, others bore horizontally, and still others will bore at various angles, depending on the complexity of the work. The maximum number of individual bits seldom exceeds 30, but special machines have been made for a large number of boring problems. The literature of the industry should be consulted for more specific information.

**Vertical Multiple Borers** carry a series of fixed or adjustably positioned spindles, usually arranged in approximately single or double vertical ranks, with a clamp-equipped work table moving up the bits. Spindles may be fixed or *rigid, i.e.*, maintain a vertical alignment with the splined drive shaft above, or *adjustable* to points at quite a horizontal distance from the plane of the drive shaft, by a telescopic universal joint (see Fig. 68).

**Horizontal Multiple Borers** differ from vertical borers principally in boring a series of horizontal holes, having a work table that moves in and out. They are used mostly for end boring. Universal-joint spindles are not generally adaptable to horizontal boring. However, adjustable multiple or cluster boring heads, to which bits are fixed in position in the head, are available.

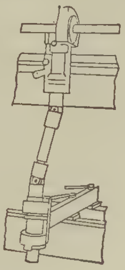

Fig. 68. Boring Mill Spindle with Universal Joint

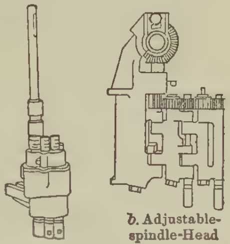

*a*. Fixed Center Cluster

*b*. Adjustable-spindle-Head

Fig. 69. Multiple Boring Heads

**Cluster Vertical Borers** (not made in horizontal types) have universal-joint spindles, adjustable over rectangular or circular areas up to 40 in. diameter, with many combinations of bits that may be attached. Motors are above, and operate the bits through gear trains which terminate in fixed sockets for spindle connections. The universal-joint spindles permit a wide range of adjustment of bits in any horizontal direction within operating limits.

**Multiple Boring Heads** are principally: 1. Fixed cluster (Fig. 69 *a*); 2. Adjustable multi-spindle (Fig. 69 *b*). Many other types of heads are made, for use in both vertical and horizontal boring machines.

**Standard Spindle Speeds** range from about 1000 to 2000 r.p.m., varying principally with the size of hole, hardness of the wood, and the rate of feed.

## Turning Machines

**LATHES** differ widely in basic principles, developing by degrees from the plain hand lathes, which is one of the oldest woodworking machines and suited to a wide range of individual work. The principle of the high-speed cutter head has been borrowed from the shaper and adapted to many lathe cuts, especially for duplicating work. Patterns and cams have been adapted from such machines as the carver, and other devices, for various other types of cut. Only the principal types are described below.

**The Copying Lathe** works entirely from a model or pattern of the exact shape required. It can be used for gun stocks, axe handles, shoe lasts, parts of period furniture, etc. The blank to be turned and the pattern are mounted on slowly rotating gear-driven centers. The cutting member is either a high-speed revolving cutter head, or occasionally a heavy saw. Its movement is controlled by a tracing pin, or roller which traverses all portions of the pattern, producing an exact duplicate. Usually the cutter moves along the length of the blank, but in axe handle lathes, the frame, with centers, blank and pattern, move past the cutter head.

**Back Knife Lathes** first turn the blank to a rough round by a ring or die with insic cutting edges, supported on a traveling carriage. The die is moved out of the way, ove the dead center, for the turning operation. The long back knife is so set, milled to such shape, that when in an angling cutting position against the blank, it gradually cuts in, an is stopped when the final turning is of the correct size and contour. The back knife neve is the exact reverse of the turning, but a mechanically developed extension of it.

**The Shaping Lathe** is an exceedingly versatile machine, turning rounds and polygona sections in almost every conceivable combination. Both lathe centers are "alive," an oscillate slowly into and out of the cutting zone, under the operator's control. Cutte knives, similar to a series of shaper heads on a single shaft, are mounted on a cutter spindl or arbor in the rear, and revolve at high speed. All knives are mounted on the arbo whether for square, round or hexagon cuts. As a general rule, where squares and round are on one turning, flat surfaces are cut first, the lathe centers turning through a small arc and keeping the work tangential to the revolving cutters by a cam. The piece to b turned is withdrawn from the cutters, turned through approximately a 90-degree angl (for a square), and the next flat surface is cut. The angle of movement controls th number of sides for squares, hexagons, octagons, etc. After the flats are completed, th rounds are turned, with lathe centers slowly and uniformly rotating. Various modifica tions may be made in this procedure for complicated types of turning or shaping piece other than turnings. The set-up of the cutter head may be so complex as to demand lon production runs for good economy.

Many different types of lathes are built in addition to the major types described above The literature of the industry should be consulted for detailed information.

## Mortising Machines

**MORTISING MACHINES** may be classed as: 1. Hollow chisel mortisers; 2. Chai saw mortisers; 3. Oscillating bit mortisers.

**Hollow Chisel Mortisers** usually provide a vertical movement of the tool into the work Horizontal types also are available. The tool (see p. 22–39) is attached directly to th motor, the rotating bit being motor-driven; the surrounding non-turning chisel is mounte in the chisel carriage on the motor frame, and both are forced together into the work. Th tables are equipped with clamps, adjustments and multiple end-gages, as several mortise may be made in the same piece. Tool strokes may be arranged automatically to repea cuts for oblong holes, up to about 50 per minute. Horizontal movement of the table als may be automatic for a series of mortises. Motor sizes range up to 4 Hp. at 3600 r.p.m Multiple hollow chisel mortisers always are horizontal stroke, limited to six heads, with minimum of 4 in. center spacing, and a maximum spacing of 72 in. between outer heads

**Chain Saw Mortisers** operate with cutting teeth mounted on the outside peripher of a link chain. The minimum size of hole is $^3/_{16} \times {}^3/_4$ in.; the maximum may b $1\,^1/_2 \times 4$ in. Longer mortises may be cut at one stroke by using a double roll bar, or b successive cuts. The table moves the work up into the chain cutters. Sprocket motor usually are 3600 r.p.m., giving the following approximate chain cutting speeds:

| | | | |
|---|---|---|---|
| No. of sprocket teeth . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . | 5 | 7 | 9 |
| Chain speed, ft. per min . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . | 1330 | 1930 | 240 |

Multiple chain saw mortisers are available up to 8 heads, which may be stationary, o adjustable in and out as well as sideways. Chain saw mortisers are not made in hor zontal types.

**Oscillating Bit Mortisers** make round-end holes, whose depth is limited by the siz of the router-type bit. The bit oscillates between stops set for the desired length Oscillations seldom should exceed 200 per min.; bit speeds are up to 7200 r.p.m. Oscilla ing motor usually is 1 Hp.; bit motors may be 4 Hp. Air clamps hold stock on the tables.

## Double-end Tenoners

**DOUBLE-END TENONERS** are highly developed machines that accomplish a wid variety of cuts at one passage of the work. Their functions have been broadened and in creased by individual motors on each cutting head, which are more flexible than the bel driven heads of earlier machines. This machine originally was intended to cut tenon simultaneously on both ends of a piece of stock. Cutting heads of various types graduall wereadded for a diversity of end and intermediate cuts.

In essential principles, the double-end tenoner consists of a sole (or bed) plate carryin two pedestals. One pedestal is stationary, and carries all operating switches. The othe may be moved along the sole plate to accommodate the work, limited in standard machine to about 90 in. Between the two pedestals, and below the work, a pair of endless feec chains, with adjustable lugs, carry the work into the saws and other cutting units. The feed-chains are kept relatively close to the pedestals, but are adjustable along a spline feed shaft between them. They are fixed in the horizontal plane, all vertical adjustments being made with the cutter heads. Two idling pressure chains hold the work firmly, operating directly above the feed chains.

For double cut-off and double rip cuts, as in plywood, only one saw is used in each pedestal. This cut is made from above. On modern double-end tenoners, the main cutter head can be tilted to make angle cuts. One or more additional horizontal (sometimes tilting) cutter heads are located on each pedestal to make end tenons, grooved, shoulder or shaper cuts on either or both sides of the stock, and at one or both ends. Each pedestal also carries a vertical cutter head. An arbor can be placed between pedestals for intermediate saws or cutters. Cope units, dado heads, relishing cutters, etc., if required, may be attached in various ways. Jump dado cams can be used to enter and withdraw dado cutters near the edge of the stock. Dovetailing attachments may be used for either male or female cuts. Methods of adjustment, attachment of various cutter heads, and other operating features vary considerably in the product of the several machine builders. The variety of work is limited only by the available cutter heads and the extent to which production runs justify elaborate set-up.

Single-end tenoners, with corresponding attachments, are available for short runs. Stock is fed on a roller feed carriage, with the cutting units at the left of the operator.

## Sanders

**POWER-FEED DRUM-SANDERS** are of two general types: 1. Work is forwarded by a rubber-cushioned endless-belt bed; 2. Work is moved ahead by pairs of pressure rollers. Widths range from 31 to 103 in. Generally, the roll-feed type sands one side only, giving thinner and more accurate surface removal as in figured faced veneers on plywood; two-side types are available, if there is plenty of surface to be removed, and accurate centering between surfaces is unimportant. Endless-bed sanders sand one side only.

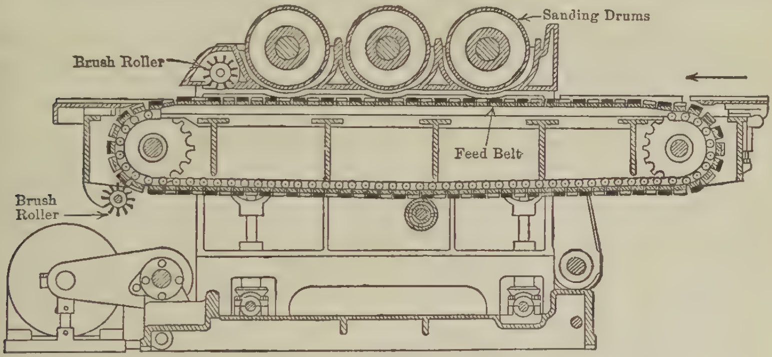

Fig. 70. Endless Bed Sander

**Endless-bed Sanders.**—In the machine shown in Fig. 70, the sandpaper drums, usually three, are on top. They are approximately 12 in. diameter, covered with felt cushion and sandpaper, sometimes wound spirally, but more often attached by clamps in slots. The feed-belt, with rubber cushions, is below. Surface speed of the first two drums usually is 3700 ft. per min. (1200 r.p.m.); that of the third drum is 5600 ft. per min. (1800 r.p.m.). Drums revolve against, rather than with the work. The work is fed at speeds ranging from 12 to 24 ft. per min. The coarsest sandpaper is on the first roll and the finest on the third roll. Each roller and the feed mechanism is driven by an individual motor. Motor sizes, depending on machine width, are: First and second rollers, 5 to 10 Hp.; third roller, 7 1/2 to 15 Hp.; feed mechanism, usually, 3 Hp. A brush roller frequently is installed at the delivery end to remove sandpaper dust. Standard drums oscillate slightly endwise (75–100 per min.), to simulate the side movement of hand sanding.

**Single-surfacing Roll-feed Sanders.**—The drum arrangement is similar to that of endless-bed sanders, except that drums are below the work, and sand through slots in the feed bed. An idler-pressure roller is above (see Fig. 71). Pairs of smooth feed rollers are located at the entering end, on both sides of the center drum, and at the discharge end. The roll type is not well suited to small dimensioned stock. The sandpaper drums are not so conveniently located for paper changing as in the endless-bed type.

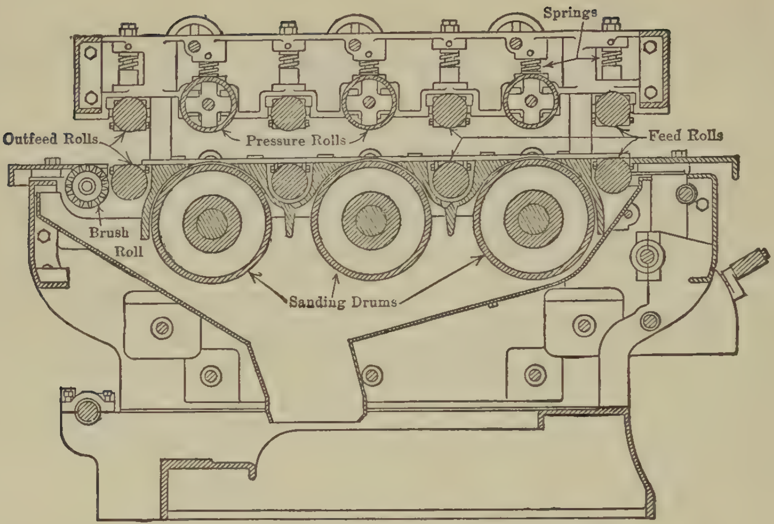

Fig. 71. Single-surfacing Roll-feed Sander

**Two-side Roll-feed Sanders.**—The upper and lower drums are directly over each other in pairs, with the same arrangement of pairs of feed rollers as in the single surface type.

**Belt Sanders** have a 6- to 8-in. endless sandpaper belt running clockwise on two 18-in. pulleys, 8 to 12 ft. apart. In the overhead type the work table, moving on ways toward and away from the operator, is below the lower belt, and the smooth side of the paper is against the pulley. In the underslung type, the table is between the belts, with the sand side of the paper against the pulley. In both types, the work is held on the table by stops at the left and an edge clamp at the right. The operator bears down on the cushion pad, hand operated or mounted on two-way sliding levers. The pad is above and applies controlled pressure through the moving sand belt to sand the stock. Belt sanders are preferred to drum sanders for work that requires a thin cut, as on plywood faces.

**Stroke Sanders** usually are used for polish and finish sanding. They are somewhat similar to belt sanders, except that the pad is mechanically reciprocated under weights. The same type of stroke machine is used for rubbing finish, the sandpaper then being omitted, and a rubbing compound used.

**Automatic Belt Sanders** for sanding mouldings consist of driven rubber feed rolls which carry the stock under a sandpaper belt, and a flexible shoe shaped to the reverse of the moulding contour. Feed is 32 to 50 ft. per min.

**Specialized Types of Sanding Machines** are: Belts on vertical pulleys for edge sanding; sand discs on rotating horizontal or vertical tables for drawers and boxes; sand drums of large diameter for curved work; sand arbors for chair legs and irregular pieces, etc. A small portable motor-driven belt sander is available for bench use.

**MANUFACTURERS** of woodworking machinery include the following (for manufacturers of saw mill machinery, see p. 22–14): E. C. Atkins & Co., Indianapolis, Ind.; Bell Machine Co., Oshkosh, Wis.; Buss Machine Works, Holland, Mich.; G. M. Diehl Machine Works, Wabash, Ind.; Henry Disston & Sons, Inc., Philadelphia, Pa.; Ekstrom, Carlson & Co., Rockford, Ill.; Charles E. Francis Co., Rushville, Ind.; Greenlee Brothers & Co., Rockford, Ill.; Hermance Machine Co., Williamsport, Pa.; Jenkins Machinery Co., Sheboygan Falls, Wis.; Leitelt Iron Works, Grand Rapids, Mich.; Mattison Machine Works, Rockford, Ill.; Mereen-Johnson Machine Co., Minneapolis, Minn.; Merritt Engineering & Sales Co., Lockport, N. Y.; J. M. Nash Co., Milwaukee, Wis.; Oliver Machinery Co., Grand Rapids, Mich.; Onsrud Machine Works, Inc., Chicago; C. O. Porter Machinery Co., Grand Rapids, Mich.; B. M. Root Co., York, Pa.; Tannewitz Works, Grand Rapids, Mich.; Vonnegut Moulder Corp., Indianapolis, Ind.; Baxter D. Whitney & Son, Winchendon, Mass.; Wilkin-Challoner Co., Oshkosh, Wis.; S. A. Woods Machine Co., Boston; Yates-American Machine Co., Beloit, Wis.

## HOISTING

### 1. MANILA ROPE HOISTING

See pp. 6-26 to 6-30 for allowable stresses, etc., of manila rope. Table 1 gives results of tests of manila rope hoists made in 1903 on a testing machine at Pencoyd Iron Works. The blocks were large, with Metaline bushed sheaves. The lead line was run through snatch blocks to simulate the course of a hoisting rope on a derrick from end of boom to engine drum. Column 5 shows overall efficiencies under best conditions. Column 6 shows probable efficiencies of the hoist alone after allowances for snatch blocks and other known losses.

**MANILA ROPE HOISTING IN PRACTICE.**—New manila rope is stiffer than used rope, friction losses due to bending are greater, and hoisting efficiency is less. Table 2 gives efficiency of manila rope hoists for new rope and used rope, based on tests and experience. Values represent efficiencies of commercial tackle blocks used in pairs under everyday operating conditions, wherein blocks are not always mounted in the best way, sheaves are relatively small in diameter, ropes are not reeved right and lubrication is neglected (Western Block Co., Lockport, N. Y.; Plymouth Cordage Co., Plymouth, Mass.). In using Table 1 to determine load capacity of a hoist, note that manila rope limber enough to show higher efficiency than new rope has lost some of its strength, and will not be as safe. *Safety in a hoist is more important than efficiency.* For instance, a 1000-lb. pull on a lead line might be rated by Table 1 to lift 3400 lb. in an 8-part hoist with new rope, and 4400 lb. with used rope, but the latter would not be so safe.

Manila rope hoists are seldom used with more than 6 or 8 parts of line. Fig. 1 shows a 6-part hoist with rope properly reeved. The lower block is at right angles to the upper, lead line 1 comes off a middle sheave in one block, and becket line 7 comes off a middle sheave in the other. A 6-part hoist has 6 parts of rope at the *movable* block.

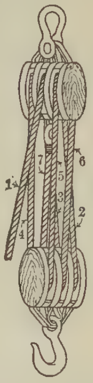

Fig. 1. Triple Tackle Block

**LOADS ON TACKLE BLOCKS.**—If lead line comes off upper block, Fig. 1, the block must carry weight lifted plus pull in the line. If Fig. 1 is reversed so that the hook block is uppermost, this block carries the weight minus pull in lead line. The reversed illustra-

**Table 1.—Efficiencies of Manila Rope Hoists in Testing Machine**

| Rope Diam., in. | Parts of Rope | Sheave | | Efficiency, Percent | | Rope Diam., in. | Parts of Rope | Sheave | | Efficiency, Percent | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | Outside Diam., in. | Groove Diam., in. | As Observed | Calculated | | | Outside Diam., in. | Groove Diam., in. | As Observed | Calculated |

| | 7 | 12 | 6 1/2 | 49 | 70 | | 9 | 16 | 9 | 39 | 61 |
| 1 1/2 | 4 | 14 | 8 | 50 | 84 | 2 | 7 | 20 | 11 | 41 | 68 |
| | 7 | 14 | 8 | 46 | 70 | | 9 | 20 | 11 | 37 | 61 |
| | 9 | 14 | 8 | 47 | 62 | | | | | | |

**Table 2.—Efficiencies of Commercial Tackle Blocks and Manila Rope**

| Parts of Rope | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|---|---|---|---|---|---|---|---|
| New rope.................. | 81 | 73 | 65 | 59 | 53 | 47 | 43 |
| Used rope.................. | 83 | 77 | 71 | 66 | 62 | 60 | 55 |

Rope sizes and corresponding block and sheave sizes are given in Table 3.

tion shows a 7-part hoist, and lead line pull is less than in a 6-part hoist where line comes off upper block.

**MANILA ROPE BLOCKS** are made in a variety of patterns for different services, as occasional or steady, slow or rapid hoisting. Table 3 gives working loads for regular-pattern manila rope blocks used in pairs. These loads are what the blocks can continue to lift safely in daily service until sheave, pin and shell are worn out. Bronze self-lubricating bushings prolong the life of sheave and block. If sheaves for hoisting rope can be hung or mounted independently of the block it is often wise to make them larger than block sheaves. The rope will last longer.

**LOADS SUDDENLY APPLIED.**—Calculations of rope hoists assume the load to be uniformly divided among all parts of rope. With many parts of rope on multiple-sheave blocks, the distribution may be unequal if load is applied suddenly, or hoist started at full speed. In such cases, a rope may break at an apparently light load.

**Table 3.—Working Loads (Pounds) for a Pair of Manila Rope Blocks**
(Western Block Co.)

| Diam. of Rope, in. | Size of Block | Diam. of Sheave | Singles | Doubles | Triples | Diam. of Rope, in. | Size of Block | Diam. of Sheave | Singles | Doubles | Triples |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 3/8 | 3 | 1 3/4 | 150 | 250 | 350 | 1 | 9 | 5 1/2 | 2000 | 2700 | 3400 |
| 1/2 | 4 | 2 1/4 | 300 | 450 | 600 | 1 1/8 | 10 | 6 1/4 | 2400 | 3100 | 3800 |
| 5/8 | 5 | 3 | 500 | 750 | 1000 | 1 1/4 | 12 | 8 | 2800 | 3700 | 4600 |
| 3/4 | 6 | 3 1/2 | 800 | 1200 | 1600 | 1 3/8 | 14 | 9 1/2 | 3800 | 4900 | 6000 |
| 7/8 | 7 | 4 1/4 | 1200 | 1800 | 2400 | 1 5/8 | 16 | 11 | 4400 | 5700 | 7000 |
| 1 | 8 | 4 3/4 | 1600 | 2300 | 3000 | | | | | | |

Extra heavy wood blocks and metal frame blocks are good for loads listed for blocks one size larger.

## 2. WIRE ROPE HOISTING

For the general theory of hoisting blocks, see p. 8–04. In practice allowance must be made for friction losses in sheaves and blocks, bending stresses in the ropes, etc.

**WIRE ROPE HOISTING.**—For wire rope, allowable stresses, fastenings and fittings, see pp. 6-34 to 6-47. Table 4 (Am. Bridge Co. Handbook for Erecting Engineers) gives lead line pull for 1000-lb. load using 6 × 19 rope on sheaves 16 in. outside diam., with Metaline bushings.

Table 4 is based on formula

$$P = Wk^n(k - 1)/(k^n - 1) \quad . \; . \; . \; . \; . \; . \; . \; . \; . \; . \; [1]$$

where $P$ = load line pull, lb.; $W$ = weight lifted, lb.; $k$ = factor from formula [2]; $n$ = number of parts of rope at movable block.

$$k = 1 + 0.225(d/R) + 0.16(r/R), \quad . \; . \; . \; . \; . \; . \; . \; . \; [2]$$

where $d$ = diam. of wire rope, in.; $R$ = radius of bending of rope on sheave, in.; $r$ = half-diam. of sheave pin, in. Both formula and table have been checked by tests and accepted by Am. Bridge Co. as practically correct. The following notes are applicable to Table 4: 1. Table is calculated for the case of the lead line coming off upper block; if it comes off lower block, divide by $k$, or increase $n$ by 1. 2. If lead line is snatched or deflected between block and hoist drum, add 8% for each 180° bend, 4% for each 90° bend. 3. Lead line should always come off a middle sheave of a multiple-sheave block, and the becket line, *i.e.*, the end of the rope that is dead-ended on a block also should lead off a middle sheave (see Fig. 1). Otherwise blocks will tip sideways, ropes will chafe, and stress in the lead

**Table 4.—Lead Line Pull Per 1000 Lb. of Load**
6 × 19 Wire Rope in Am. Bridge Co. 16-in. Blocks with 2-in. Pin

| No. of Parts $n$ | 5/8-in. Rope | 3/4-in. Rope | 7/8-in. Rope | 1-in. Rope | No. of Parts $n$ | 5/8-in. Rope | 3/4-in. Rope | 7/8-in. Rope | 1-in. Rope |

| 10 | 124 | 126 | 128 | 131 | 20 | 74 | 76 | 79 | 81 |
| 11 | 115 | 117 | 119 | 122 | $k$ = | 1.041 | 1.045 | 1.048 | 1.052 |

line will be greater. Dynamometer tests with a 13-part hoist lifting 60 tons showed a 20% increase in pull with lead and becket lines reeved from outside sheaves. 4. Wire rope sheaves are listed by outside diameter. Diameter at bottom of groove is about 2 in. less. 5. In lowering a load by slackening on lead line, friction and bending effects are reversed as compared with hoisting. The relation between $P$ and $W$ is found by substituting $1/k$ for $k$ in formula [1]. Hoists having many parts of line may require weight to be added to lower block to make it overhaul the lead line if latter is long or much deflected. 6. Table is calculated for Am. Bridge Co. standard blocks with 16-in. sheaves on 2-in. pins. Values of $k$ range from 1.041 for 5/8-in. rope to 1.052 for 1-in. rope. For other combinations of rope, sheave and pin, $k$ may be calculated and interpolated in Table 4. Within limits of Table 5, giving commercial sizes of wire rope sheaves for 6 × 19 rope, it is unnecessary to calculate $k$. For these sizes of sheaves in standard blocks, lead line pulls from Table 4 may be taken as correct within 5%, as qualified below.

**EFFICIENCY OF WIRE ROPE HOISTING.**—Table 6 shows percentage ratio of theoretical to actual pull (called efficiency), based on Table 4. Values in Tables 4 and 6 probably represent the best that can be obtained in wire rope hoisting. Loads in the Am. Bridge Co. tests were from 20 to 60 tons, riggers were skilled and operating conditions good. Makers' tests of tackle blocks with lighter loads show lower efficiency. Table 7 gives test results that represent average practice in wire rope hoisting.

Table 7 refers to 6 × 19 wire rope used with manufacturers' standard blocks carrying sheaves of sizes shown in Table 5 as related to rope diameters, fitted with self-lubricated bronze bushings.

Considering only life of rope, sheaves of commercial tackle blocks are of too small diameter; practically, it is inconvenient to make them larger. Some single blocks for whip or rapid cargo hoisting have construction refinements, making the blocks safer, more durable and less troublesome, and add life to the rope. Sheaves are relatively large, of manganese steel, with ball or roller bearings. Shells are cast-steel with heat-treated alloy steel pins.

**WIRE ROPE BLOCKS** are made as regular, heavy, and extra heavy, with hook (lower block, Fig. 1) or shackle (upper block, Fig. 1) connections. Shackles are used for permanently-attached blocks, and hooks for detachable blocks. Hooks fail by straightening, thus giving notice of overloading before failure. Shackles fail by shearing the pin at loads about 5 times those at which round iron hooks straighten, size for size. Hooks flattened to give more depth of cross section at the back are 10 to 15% stronger than hooks

**Table 5.—Commercial Sizes of Wire Rope Sheaves**

bent from round bars. Drop forged hooks are more generally used and are even stronger. Table 8 gives recommended working loads for a pair of wire rope blocks. Recommended working loads refer both to ultimate strength of block and its parts, and to durability and safety of block in use.

**STRESSES IN HOIST ROPES** depend on load, acceleration or retardation of load, and stresses due to bending over sheaves and drums. The factor of safety is intended to cover other items, accidental or incidental. For bending stresses, see Table 11. If a load $W$ (including weight of rope), starting from rest, is brought to velocity $V$ in distance $D$ by uniformly accelerated motion, rate of acceleration is $V^2/2D$; since $f = Wa/g$, the added pull required to bring the load up to speed is $f = WV^2/2gD$.

Example.—To accelerate a 10-ton load from rest to 20 ft. per sec. in 10 ft. requires $(10 \times 2000 \times 400)/(64.3 \times 10) = 12{,}440$ lb. plus 20,000-lb. load. The rope is under the same stress if the hoist brake is applied to reduce the speed from 20 to 0 ft. per sec. within 10 ft. of travel.

If rope slack is wound in at full speed, the sudden increase in stress when load comes on may injure or break the rope, unless it is long enough to absorb the shock by its own elasticity. Table 9 gives results of dynamometer tests on taking up slack at full speed. Speed and length of rope are not stated.

**STRESSES ON INCLINES.**—A rope pulling a load up an incline is stretched to a tension

$$T = (W + R)\sin\alpha + WF\cos\alpha + Rf\cos\alpha, \qquad [3]$$

where $W$ = weight of load, usually a car or cars; $R$ = weight of rope; $\alpha$ = angle to horizontal of incline; $F$ and $f$ = respectively, coefficient of friction of cars on track and of rope friction over rollers. Table 10 gives tension required to pull 2000 lb. up inclines of various slopes; $F$ (assumed) = 2 1/2%; $f$ = 5%.

For descending loads, $T = (W + R)\sin\alpha - WF\cos\alpha - Rf\cos\alpha$. For the added pull for acceleration or retardation on an incline substitute $T$ for $W$ in the acceleration formula. For speeds under 500 ft. per min., allow 5% to cover acceleration stress. For speeds of 500 to 1000 ft. per min., allow 10%; for higher speeds, calculate it.

**BENDING STRESSES IN WIRE ROPE.**—A standing rope bent over a thimble or eye loses some strength, as the bent wires do not all share in taking load. Such a rope shows, in a testing machine, strength of 88 to 90% that of straight rope. A standing rope bent over a sheave of a size in common use may lose 5% strength.

Running ropes have a similar loss. A greater loss comes from wire breakage due to fatigue of metal. Fatigue depends on the number of bends, that is, on velocity of the rope, and also on bending stress on outside wires. Magnitude of stress due to bending is impossible of direct calculation or estimation; various formulas give discordant results. James F. Howe (*Trans.* A. S. M. E. vol. xl, p. 1043, 1918) tested many sizes and kinds of wire rope. The data were used in a formula giving values shown in Table 11, which represent a stress to be added to direct tension to show equivalent total load on the rope.

**Table 9.—Rope Stresses in Mine Hoists—Taking Up Slack at Full Speed**

(Trenton Iron Co.)

Values must be regarded as comparative only and not absolute. The principal value of the table is to suggest fatigue effect due to bending. High bending stress with respect to direct load means relatively short life of rope. Low bending stress as compared with direct load prolongs the life of rope. One maker says that if in calculating rope stresses the total static load is increased by force necessary to accelerate it to maximum rope speed, and if sheave and drum diameters accord with good practice, bending stresses will have little effect on safety of the rope or economy of operation. C. D. Meals (*Trans. A.S.M.E.*, MH–51–5, 1929) gives diagrams and tables to show comparative effects of bending in wire rope of various constructions.

Fatigue of metal is more rapid if rope is subjected to reverse bending. Reverse bends should be avoided if possible; if not, all sheaves should be made larger than ordinary.

If a hoisting rope runs direct from drum to load, Fig. 2, each part of the rope makes one bend in wrapping on the drum and one bend in leaving it, a total of 2 bends for the cycle of hoisting and lowering. In Fig. 3 the rope makes 8 bends and 2 reverse bends per cycle, and the wear on rope, due to bending, will be at least 5 times that of Fig. 2; the reverse bends of Fig. 3 will make the ratio still more unfavorable.

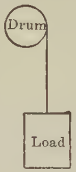

Fig. 2

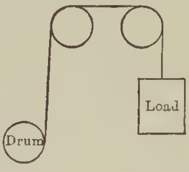

Fig. 3

Small equalizer sheaves used with double ropes on hook blocks on cranes often cause wire breakage. The motion of the rope on the sheave is slight, bending is concentrated on a short length of wire and breakage results. Some makers use equalizer bars instead of sheaves. One rope is fastened to each end of the bar.

Internal wear in the rope due to wires and strands sliding on each other can be reduced by proper lubrication. Tests of 9/16-in. plow steel ropes showed that a lubricated rope run over a 10-in. sheave made 2 1/2 times as many turns as a dry rope before the rope failed; over a 24-in. sheave, 5 times as many.

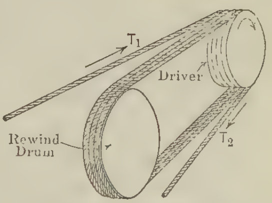

Fig. 4. Winding Machine Drive

**DRUMS AND SHEAVES FOR WIRE ROPE.**—A wire rope may be used for hoisting haulage or power transmission in various ways:

1. By winding on a drum, grooved or smooth, in one or more layers. The drum may be cylindrical, a frustum of a cone or a combination of the two. Winding on a drum generally is used in hoists and in haulage back and forth.

2. By winding on a winch head. Rope leads on a large diameter, makes several wraps and pays off on a smaller diameter. Tension is applied to the slack rope. Under load, a side slip tends to wear rope and winch head. This method is used on capstans, car pullers and for intermittent hoisting and hauling.

3. By winding several wraps of an endless rope on a concave-faced drum or sheave shaped like a winch head. Tight side of rope leads on a high diameter; slack rope leads off a low diameter to a tail sheave to which tension is applied. The side slip of the rope on the drum is objectionable and this method is not used widely.

4. By winding and rewinding an endless rope around a pair of grooved drums, and from drums to a tail sheave to which tension is applied. This method is used in endless rope hauling, in traction drives for high-speed elevators, etc. See Fig 4. If $T_1$ = ten-

sion in rope leading to main drum, and $T_2$ = slack tension in rope coming off drum, then

$$T_1 = T_2 \times 10^{0.00758f\theta} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [4]$$

where $f$ = coefficient of friction between rope and drum, $\theta$ = total angle of wrap on the driving drum, deg. of arc. In Fig. 4, $\theta = 720°$. For discussion of this formula, see p. 24–14. For values of $f$, see p. 8–24. If rope runs in V-shaped grooves, bears on the sides only and does not touch the bottom, the increased coefficient of friction, $f_1 = f/(\sin V/2)$. Angle $V$ between sides may be from 25° to 45°. The smaller this angle, the larger the friction and the greater the value of $T_1$ for a given value of $T_2$, but the wear on rope and groove from slip, creep and motion at engagement and disengagement may be destructive if the load is great or the hours of service long.

5. By tractive effort of a sheave with grooves lined with wood, leather or rubber friction blocks. This method is used for power transmission with high-speed wire ropes. Such large diameter sheaves used with counterbalanced mine cages is the Koepe system of hoisting. See Peele, Mining Engineers' Handbook (John Wiley & Sons), and catalogs of wire rope makers.

6. By the use of a grip sheave. Within the rim of the sheave pairs of jaws hinged together are spaced. As they yield to the pressure of the rope they grip it. Springs open the jaws at point of disengagement. This method is used for endless rope carhauls for rope tramways. Older forms of grip sheaves have been known to cut and break ropes; for an improved form (Am. Steel and Wire Co., Worcester, Mass.) see *Trans.* A.S.M.E. 1931, MH-53–1.

German hoisting machinery uses several forms of grip sheaves; the sheave is parted along the axis of the rope, and the two parts squeezed together to exert pressure on the rope. Another German device obtains tractive force from a single drum. The rope wraps several times around a plain cylinder but rests in grooves in sections of a link chain, which hangs loose and is pushed across the face of the drum by auxiliary mechanism. Another method is to wind the rope around two drums (Fig. 4) and drive both drums through gearing which equalizes the work on each drum. See *Fördertechnik*, 1929–1932.

**SHEAVE AND DRUM SIZES.**—The larger the diameter over which rope runs, the longer will it last, but the cost and trouble of renewing rope usually is less than the difficulty of accommodating larger drums and sheaves and the greater weight and cost of heavier machinery. Such cases are tackle blocks, small hoists, shop cranes, derricks, dredges, excavators, etc.

Ropes on small sheaves and drums are subjected both to a larger stress due to direct bending (see Bending Stresses), and pinching of wires and strands on each other, preventing free movement; also, they may be nicked and broken by the pressure. When a rope runs over a sheave, the tightening of the outer wires tends to twist the rope. The smaller the sheave, the greater is the twist, and also the greater is the unit pressure of the rope on the sheave tread. This twist under pressure causes the rope to cut the sheave, producing sharp edges which wear away outer wires and shorten rope life. To avoid this trouble cast-steel sheaves should be used. Manganese-steel sheaves, ground true in the groove, are still better. C. D. Meals (*Civil Engg.*, 1930) gives a table of allowable pressures for various kinds of rope on cast-iron, cast-steel or manganese-steel sheaves. One way to destroy a new rope is to run it on sheaves worn and corrugated by an old one.

Table 12 gives in the form of ratios of sheave or drum diameter to rope diameter, the following: 1. Critical diameters; those which pinch the rope and prevent free movement of strands. Rope has short life under such conditions. 2. Minimum economical diameters; these should be chosen where sizes of sheaves and drums are not limited by considerations of available space or weight of parts, and where economy in the use of rope is important. 3. Desirable diameters; those recommended for heavy work in important installations, as mine hoists, skip hoists, heavy cranes, hot-metal cranes, and in places where safety is important, and where shut-down from rope breakage cannot be tolerated. The table refers to cast-steel ropes which tests as wire about 180,000 lb. per sq. in. Ropes of stronger steels are stiffer, harder and cost more. They should be used with larger sheaves and drums. If of improved or special cast-steel, good for 200,000 lb., $^1/_9$ larger;

**Table 12.—Diameter Ratios of Sheaves and Drums for Cast-steel Running Ropes**

| | 6 × 7 | 6 × 19 Seale | 6 × 21 Seale<br>6 × 19 Warrington | 6 × 19 Filler Wire | 6 × 31 Seale | 6 × 37 | 8 × 19 Warrington | 8 × 19 Seale | Tiller |

| Desirable Ratios............ | 72 | 50 | 45 | 42 | 38 | 27 | 31 | 42 | 20 |

if of plow steel, good for 210,000 lb., $^1/_6$ larger; if of improved plow steel, good for 240,000 lb., $^1/_3$ larger. See Bending Stresses.

**PROPER GROOVE CONTOUR.**—Groove diameter as measured by template or gage should be slightly larger than rope diameter. New ropes are slightly over size, and for a proper fit groove diameter as measured by template should be larger than nominal rope diameter as follows: $^1/_2$-in. rope and smaller, $^1/_{16}$ in.; $^9/_{16}$- to 1-in. rope, $^3/_{32}$ in.; 1 $^1/_{16}$- to 2-in. rope, $^5/_{32}$ in. See Fig. 5.

As metal wears away in the tread or bottom of groove, and as rope wears smaller in diameter there is a new condition of fit, with groove diameter equal to that of the worn rope. See Fig. 6. If a new rope runs over worn sheaves, it will not fit the worn groove with proper clearance but will be jammed into it, preventing free movement of the rope, and concentrating abrasion on two lines. Also, there will be a tendency to distort the shape of the rope and cause nicking and breaking of wires. Rope diameter is the largest diameter outside of strands.

**DETERIORATION OF WIRE ROPE.**—Ropes deteriorate by: 1. Frictional wear. 2. Breakage of wires due to defects of materials. 3. Breakage due to bending stresses. 4. Corrosion, inside and outside. 5. Fatigue in steel in the wires. All defects finally show as broken wires, and their appearance guides decisions of when to discard a rope. After a new rope has been put in service, the crowns of outside wires wear to an extent necessary to form a wearing surface or contact area to support the rope on sheaves and drums. The reduction in strength of rope is slight and need not cause concern if wear is slow. The appearance of broken wires does not necessarily indicate rapid deterioration. If the rope has started with the proper factor of safety, early abrasion and breakage of wires may be considered normal deterioration within safe limits, but when broken wires continue to appear regularly, removal of the rope should be considered.

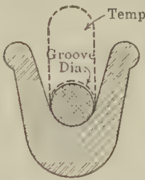

FIG. 5. Correct Design of Rope Groove

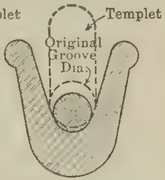

FIG. 6. Correct Design with Rope Worn

Safety of operation depends on strength of the rope as it nears the time of removal. The factor of safety at this time is hard to determine; it depends both on wear and breakage of visible outside wires, and on corrosion and breakage of invisible inside wires. These combine to cause a reduction in diameter of the rope, which, when greater than wear on outside wires would account for, may indicate internal corrosion. *Coal Age*, Nov. 1924, reports a 1 $^3/_8$ in., 6 × 19 mine hoist rope regularly inspected and reported in good condition, which suddenly broke at the part in contact with the head sheave, with cage at bottom of the shaft. Examination of the broken ends showed internal corrosion due to entrance of water; the hemp core was crushed to a pulp 10 ft. on each side of break and rope diameter was reduced from 1 $^3/_8$ in. to 1 $^9/_{32}$ in.

If a rope has not been corroded, its remaining strength may be estimated by counting broken wires in one rope lay in the worst part of the rope, and measuring amount of metal removed by abrasion of outside wires. In one rope lay all outside wires in that length of rope can be seen. Most of the strength of the rope is in these wires, ranging from 83% for 6 × 7 rope to 57% for 6 × 19 Warrington rope. John A. Roebling's Sons Co. publishes charts which show, from observed facts of breakage and abrasion, the remaining strength of a used rope, provided there is no internal corrosion. Amer. Cable Co. publishes tables telling when ropes in various kinds of services should be discarded. These tables may be summarized as follows: Rope should be discarded when in one rope lay from 8% to 20% of visible wires are broken; or when 15% to 25% of wires in one strand are broken, especially if they are adjacent wires; or when outside wires are worn to $^1/_2$ or $^2/_3$ of original diameter. For high-speed work, heavy loads, and when risk to life or property must be kept low, the lower percentages are recommended. If breakage of a rope merely means a machine stoppage, ropes can be run until outside wires are worn off or until a strand breaks.

Rules and tables for discarding ropes are suggestive only. For instance, it is not possible to group all shop cranes in one class. It is better to treat each installation separately, examine rope systematically and regularly, note and record breakage and wear of wires. A minimum life based on observed facts can be set up as a standard; if tensile tests of parts of discarded rope show it to have more than requisite strength, considering a proper factor of safety, a new basis can be set up. After a few ropes have been discarded and tested, a standard for that installation can be established that will allow rope to be used with safety and economy.

**EARLY FAILURE OF WIRE ROPE.**—Faults which appear early in the use of a rope should not be laid always to poor manufacture. Careless handling and reeving of the rope often is responsible. The life of a rope often can be increased by putting an obligation of responsibility and competition on the men whose duty it is to use it. (*Proc.* A.S.C.E. May, 1932).

Tech. Paper 237, Bureau of Mines, 1919, gives valuable information on use of rope in mine hoists. It suggests: 1. If one broken wire is found in a rope at a socket fastening, socket should be cut off and renewed. 2. Even if no broken wire is found at a socket or thimble it should be renewed at intervals of not over 4 months, depending on life of rope in service. 3. Bolts in clip fastenings must be kept tight. 4. After 3 yr. in service, even if idle, rope should not be used unless tested for ultimate strength. 5. Safety factor must never be less than 4 $^1/_2$. 6. Ropes of 6 × 19 construction must be discarded when 6 broken wires occur in one rope lay, or when outside wires are worn to $^2/_3$ original diameter. 7. It is better to err on the side of safety than to prolong life of a rope. Accidents generally cost more than new rope.

A Research Committee of the A. S. M. E. is (1936) co-operating with the U. S. Bureau of Standards to establish by tests of used rope a relation between observed facts of wire breakage and abrasion and the strength remaining in the rope.

**ATTACHING WIRE ROPE.** (Tech. Paper, 237, Bureau of Mines.)—The rope may be attached to its load by a socket, Fig. 7, or it may be bent back on itself to form an eye and the loose end clamped to the rope with rope clips, Fig. 8. Properly done, the first method develops the full strength of the rope, but has as disadvantages: poor workmanship is concealed; it cannot be readily inspected; the rope is rigidly held and the effect of bending is concentrated just above the socket; it is more difficult to make. Fastening by clips develops not over 85% of the strength of the rope. It bruises and crushes the rope where the clips are applied, and is liable to slip, but it can be readily inspected, and requires little skill in making. Rope makers recommend the socket method of fastening, which, if made according to instructions, never fails. After either a socket or clip attachment is made it should be tested by making several trips under a heavy load before men are allowed to ride.

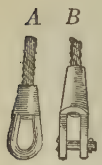

Fig. 7. Socket

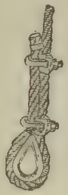

Fig. 8. U-bolt and Clip

Fig. 9. Thimble

Methods of Attaching Wire Rope

The clip attachment is made as follows: The rope is bent back over a thimble of the proper size and the loose end clamped against the long end of the rope with the proper number of clips. The Crosby type of U-bolt-and-drop-forging clip has proved most satisfactory. The clips should be spaced a distance apart of 6 times the rope diameter, the drop forging being against the long end and the U-bolt against the loose end of the rope. The number of clips required to develop approximately 80% efficiency of the rope and the proper length of wrench to tighten the bolts are given in Table 13. Never put the drop forging of the clip against the loose end of the rope.

The clips must be carefully inspected occasionally and tightened if they show any signs of loosening through the reduction in diameter which comes from stretching of the rope and compression of the hemp core.

Thimbles (Fig. 9) may be held in the bend of the rope by clips or they may be spliced in. A spliced end, properly made, will not pull out, but it will not develop the full strength for $^1/_2$-in. rope, and not over 60% for 2 $^1/_2$-in. rope. Thimbles and sockets form the means of attachment of hooks and shackles and eyes of various kinds. See Figs. 12, 13 and 14. For high tensile ropes (plow-steel, etc.), it is best to use the special heavy thimbles and sockets listed by wire rope makers.

**FASTENING WIRE ROPES TO DRUMS.**—Fig. 10 (Link-Belt Co.) shows a method of readily attaching or detaching the rope from the circumference of a drum on an electric hoist. The last groove sweeps with a large radius into a depression which allows the socket on the end of the rope to be slipped into the inside of the drum; a pipe plug closes the cavity and locks the socket in place. By unscrewing the plug, the socket can be pulled out and the rope removed.

Where the end of the drum or its hub is readily accessible the rope can be secured by a few wraps around the hub with the end clipped to itself or to one of the arms or spokes of the drum.

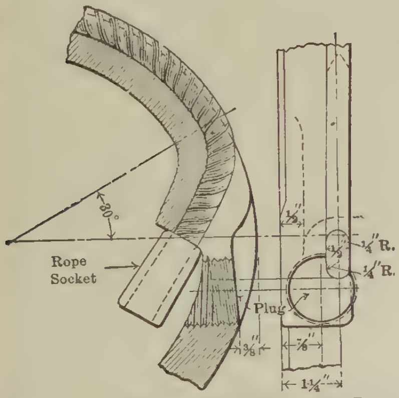

FIG. 10. Method of Fastening Wire Rope to Drum

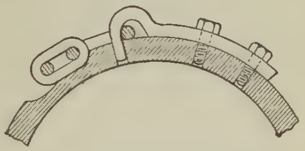

FIG. 11. Method of Fastening Chain to Drum

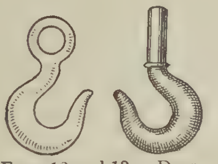

FIGS. 12 and 13. Drop Forged Hoist Hooks

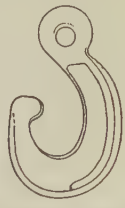

FIG. 14. Bemis Safety Hook

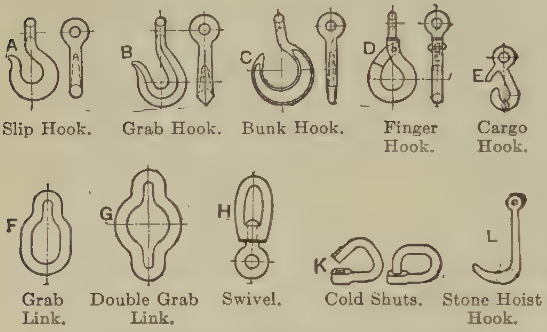
The hole in the rim through which the rope passes should be well rounded to avoid a sharp kink in the rope. Wherever possible the drum should be cast with a ledge or lug to lead the rope tangent to the hub over a radius of 6 or 8 diameters of the rope (similar to Fig. 10). To fasten the end link of a chain to a drum, it is customary to use a forged clamp, tap-bolted to the rim of the drum, and provided with a finger equal in diameter to the size of the chain. (Fig. 11.)

**DROP-FORGED HOIST HOOKS** of steel without welds are made in sizes up to 25 tons capacity. They are heat treated after forging and tested to 50% beyond rated working load. See Figs. 12 and 13 and Table 14. Drop forge companies have stock dies for most sizes and furnish hooks in moderate quantities without making charge for dies. Drop-forged hooks of dimensions in Table 14 are good for loads of 3 1/2 to 5 times rating, if sling or fixture rests in the bottom of the jaw. If the load improperly comes on the point of the hook, the carrying capacity is much less. In no event is the hook apt to break suddenly; the jaw will open out first, and signify overloading or improper engagement of the hook.

The Bemis patent safety hook, Fig. 14, (Am. Loco. Co., New York) has rated capacities up to 14,000 lb. It is made in four sizes. Hooks fitted with movable guards are not favored by stevedores. They are apt to get out of order and time is lost in putting slings on or off.

Fig. 15 shows various forms of forged connections used with hoists and slings. *A* is a slip hook used on end of rope or chain sling passed around a load to tighten on the load when hoisted. *B* is a grab hook used on chain slings which are not to tighten on the load; the throat of the hook allows the chain to enter but not to slip. *C* is a bunk hook used on tackle to take several rope slings at one time. *D* is a finger hook to avoid the danger of the hook catching under the edges of hatches in ships. *E* is a cargo hook for the same purpose. *F* is a grab link used instead of a grab hook; one end of the chain sling is fastened to the large end of ring; the chain is passed through and when the loop is of proper size the small end of the link is pulled between two links of chain. *G* is a double grab link used to shorten a chain or join two quickly and temporarily. *H* is a swivel used to prevent twisting of load by twisting of the hoisting rope or chain. *K* is a cold-shut for repairing a chain or connecting two chains. *L* is a stone hoist hook, used in quarry work; the points of the hooks engage the sides of the stone blocks.



Slip Hook. Grab Hook. Bunk Hook. Finger Hook. Cargo Hook.

Grab Link. Double Grab Link. Swivel. Cold Shuts. Stone Hoist Hook.

FIG. 15. Forms of Forged Connections Used with Hoists and Slings

Steel for hooks, rings and hoisting fixtures should be of known analysis. Test specimens should be subjected to bending to insure absence of pipes, seams or other imperfections in the bar. Hot-rolled steel of forging quality, S.A.E. specification 1010 is used by some makers.

In one important works all chains, slings, hooks and lifting fixtures are inspected once a month; parts that can be benefited by annealing are so treated once a year (*Iron Age*, May 22, 1930).

**WIRE ROPE SLINGS**, as compared with chain slings, are lighter and, in general, will not fail without warning. Breakage of outer wires is the visible warning, but the inner wires alone will carry loads at which the slings are rated by the makers.

Plain slings are made of standard 6 × 19 or 6 × 37 rope spliced endless, or fitted with sockets, thimbles or eye ends. In the Atlas patent slings (MacWhyte Co., Kenosha, Wis.) each member consists of one right and one left lay rope braided around a hemp core back and forth, so that the sling member has a strength of 8 or more strands of the rope. See Fig. 16. The ends are loops which can be used as eyes, or fitted to sockets or thimbles. In the Drew sling, made by the same company, an endless wire rope is braided into a band

**Table 15.—Plow Steel Wire Rope Slings**

(John A. Roebling's Sons Co., Trenton, N. J.)

The safe load for any number of parts may be obtained from values given below by direct multiplication. Slings 3/8 in. to 1 1/8 in. diameter inclusive, 6 × 19 rope; slings 1 1/4 in. diameter and larger, 6 × 37 rope.

about 2 rope diameters thick, 6 or more diameters wide. John A. Roebling's Sons Co., Trenton, N. J., makes slings whose members are of "grommet" construction, *i.e.*, one strand braided back on itself to form a 6- or 7-strand rope, endless except for a splice in the one strand. The ends preferably are held by patented thimbles, which are large, permit some slip to equalize the load, and in the form shown in Fig. 17, one thimble can be passed through the other to form a loop or anchor sling. The grommet link, Fig. 18, avoids using a forged steel ring to connect the two legs of a sling. All tension comes on a wire rope ring spliced endless as described above.

Fig. 19 shows a sling with clamp hooks for lifting plate. It has an endless grommet with 3 equalizing thimbles, and carries plate clamps with a positive grip. Structural steel slings may be fitted with a toggle and releasing pin for detaching the sling, when slack, by pulling a hand line from a distance.

Fig. 16. Atlas Patent Sling

The rated carrying capacity of a sling depends on the kind of fittings, the way the sling engages the load and other factors obtained by experience. Table 15 gives carrying capacities of plow-steel slings which bind against the load. If the sling does not come in contact with the load or if it passes around a large diameter, so that stresses are not concentrated at corners, safe loads may be increased somewhat above the tabular figures.

# HANDLING MATERIAL IN BULK

## 1. WIRE ROPE HAULAGE

Wire rope haulage is less important now than in the days before the general use of electric mine locomotives, chain carhauls, coal conveyors, etc. The following is abridged from publications of John A. Roebling's Sons Co., and The American Steel & Wire Co.

**SYSTEMS OF WIRE ROPE HAULAGE** are: 1. Self-acting inclined plane, used on grades where the descending loaded cars raise the empty cars. 2. Engine plane, where a reversible hoisting machine and a single wire rope are used to raise and lower cars on a slope. 3. Tail rope system, consisting of a reversible hoisting machine with two drums, clutches and brakes, a main rope hitched to the cars to pull them in one direction and a tail rope hitched to the other end of the train to pull them in the opposite direction, the brakes on the drums being used to check the speed of the cars on down-grades and prevent them from overrunning the forward rope. 4. Endless rope system, used in mines, on piers, and at coal and ore storage plants for moving railroad cars. The rope is driven by a grip sheave, or it is wrapped a number of times between the driving drum and a rewind (or back) drum mounted on the engine base, the number of half-wraps on the driving drum being sufficient to prevent slipping under load. The cars are attached to the rope at any place by hand-operated grips and can be detached by the same means without stopping the rope. The driving contact between drum and rope must be maintained by tension applied to the rope by a weighted sheave somewhere in the circuit. The weight $W = T + S$, where $T$ and $S$ are the tensions in the tight and slack sides, respectively. The resistance of cars, rope, idlers, etc., $= R = T - S$. Then to prevent slip, $W = KR$, where $K$ is a factor depending on the coefficient of friction between rope and drum, and on the number of half-wraps. Values of $K$ are given in Table 1. In general,

$$T = R(K + 1) \div 2$$

The increase in tension in the endless rope, compared with the main rope of the tail-rope system, where the stress in the rope is equal to the resistance, is about as follows, assuming $f = 0.400$:

| | | | | | | |
|---|---|---|---|---|---|---|
| $n$ = | 1 | 2 | 3 | 4 | 5 | 6 |
| Increase in tension in endless rope, compared with direct stress, % | 40 | 9 | 2 1/3 | 2/3 | 1/5 | 1/10 |

These figures are useful in determining the size of rope. For instance, if the rope makes two half-laps on the driving drum, the strength of the rope should be 9% greater than a main rope in the tail-rope system. The values of $f$ below are coefficients of friction between rope and drum.

| | Dry | Wet | Greasy |
|---|---|---|---|
| Wire rope on a grooved iron drum, $f$ | 0.120 | 0.085 | 0.070 |
| Wire rope on wood-filled sheaves, $f$ | 0.235 | 0.170 | 0.140 |
| Wire rope on rubber and leather filling, $f$ | 0.495 | 0.400 | 0.205 |

The importance of keeping the rope dry is evident from these figures, but calculations should allow for wet ropes in most cases.

**WIRE ROPE TRAMWAYS,** or simply **Ropeways** are transporting systems in which moving carriers or containers hang from a wire rope carried on a series of spaced supports, and are moved along by a rope, generally from one terminal to another. Ropeways which both hoist the load and carry it are cableways.

For distances over a few hundred feet a ropeway often is the best, cheapest, and sometimes only means of transport. Under favorable conditions it is low in first cost, cheap to operate, and maintenance and depreciation are low. Ropeways are durable and serviceable. One European builder says (1932) that over 90% of those built by him in the past 30 years are in use; of those built within 50 years, 75%. A ropeway 18 miles long carrying 36,000 tons a year at one-third the cost of transportation by truck is described in *Trans.* A.S.M.E. 1929, MH–51–2. Tramways are single rope and double rope.

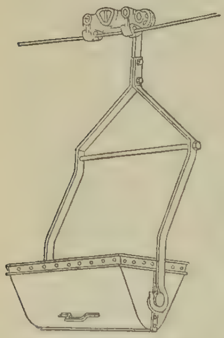

FIG. 1. Single Rope Tramway Carrier

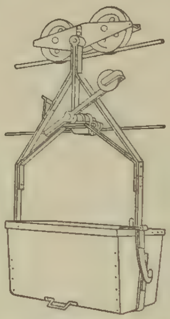

FIG. 2. Double Rope Tramway Carrier

**Single Rope Tramways** comprise one endless moving rope which both supports and moves the carriers (Fig. 1). At the driving terminal is a large grip sheave (see p. 23-08) or a multiple-groove sheave working with a rewind sheave (see p. 23-07). At the other end of the line, an idler sheave with a pull-back weight puts tension in the rope. Towers on the run carry sheaves to support rope and carriers. The carrier has a pair of clamps to grip the rope. In one construction (Pohlig) the grip permits some axial rotation of the rope, to lessen wear on grip and rope. Grips are automatically engaged or disengaged at terminals, and the carrier runs on its own rollers over fixed track to be loaded or unloaded. Ropeways are best built in a straight line, but angle stations can be provided. Single-

**Table 1.—Values of Coefficient $K$**

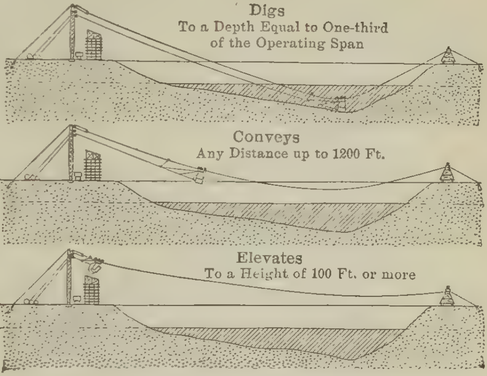
| $f$ | $n$ = Number of Half-laps on Driving-wheel | | | | | |
|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 |
| 0.070 | 9.130 | 4.623 | 3.141 | 2.418 | 1.999 | 1.729 |
| .085 | 7.536 | 3.833 | 2.629 | 2.047 | 1.714 | 1.505 |
| .120 | 5.345 | 2.777 | 1.953 | 1.570 | 1.358 | 1.232 |
| .140 | 4.623 | 2.418 | 1.729 | 1.416 | 1.249 | 1.154 |
| .170 | 3.833 | 2.047 | 1.505 | 1.268 | 1.149 | 1.085 |
| .205 | 3.212 | 1.762 | 1.338 | 1.165 | 1.083 | 1.043 |
| .235 | 2.831 | 1.592 | 1.245 | 1.110 | 1.051 | 1.024 |
| .400 | 1.795 | 1.176 | 1.047 | 1.013 | 1.004 | 1.001 |
| .495 | 1.538 | 1.093 | 1.019 | 1.004 | 1.001 | ..... |

rope tramways are used for relatively light loads, which can be spaced with some regularity, and where grades on the line are not over 30%.

**Double Rope Tramways** are those most used in the U. S.; they are suited to a wider variety of loads, grades and spans than single rope tramways. They have two track cables, one for loads, one for empties, usually of locked coil construction (see p. 6-42) anchored at one end, with tension weights at the other. The carriers, Fig. 2, have rollers running on the track cables and are pulled along by a hauling rope which they grip. The hauling rope is driven, tensioned and supported as is the rope of a single rope tramway. The grip is worked by two jaws on a threaded pin to which a lever is attached. At the terminal a stop throws the lever over and tightens or loosens the clamp.

Wire rope tramways are built by manufacturers [4], [13], [71], [78] listed on p. 23-81, and others. For details of American ropeways, see Peele, Mining Engineers' Handbook (John Wiley & Sons) and makers' catalogs. For European practice, see P. Stephan, Die Drahtseilbahnen (Julius Springer, Berlin). Costs of handling are compared with costs by other methods in *Trans.* A.S.M.E., 1930, MH–52–4. See also *Trans.* A.S.M.E., 1931, MH–53–4, E. J. Lloyd, on recent improvements in automatic dumps, etc.

**SUSPENSION CABLEWAYS OR CABLE HOIST-CONVEYORS** are systems of hoisting and transporting materials consisting of one or two track cables stretched in one span between terminals, a bucket, container or grab suspended from a carriage running on the track cable, ropes for hoisting the suspended load and moving the carriage, and winding drums for the ropes. In quarrying, rock-cutting, stripping, piling, dam-building, and many other operations where it is necessary to hoist and convey large individual loads economically it frequently happens that the application of a system of derricks is impracticable, by reason of the limited area of their efficiency and the room which they occupy. To meet such conditions cable hoist-conveyors are used, as they can be operated in clear spans up to 1500 ft., and in lifting individual loads up to 15 tons. Two types are made—one in which the hoisting and conveying are done by separate running ropes, and the other applicable only to inclines in which the carriage descends by gravity, and but one running rope is required. The moving of the carriage in the former is effected by means of an endless rope, and these are commonly known as "endless-rope" hoist-conveyors to distinguish them from the latter, known as "inclined" hoist-conveyors.



Digs
To a Depth Equal to One-third of the Operating Span
Conveys
Any Distance up to 1200 Ft.
Elevates
To a Height of 100 Ft. or more

Fig. 3. Slackline Cableway

The general arrangement of the endless-rope hoist-conveyors consists of a main cable passing over towers, A-frames or masts, as may be most convenient, and anchored to the ground at each end. Cable tension is maintained by a turnbuckle at one anchorage.

The carriage travels on this cable. It is moved back and forth by means of the endless rope. The hoisting is done by a separate rope, both ropes being operated by an engine specially designed for the purpose, which may be located at either end of the line, and is constructed in such a way that the hoisting-rope is coiled up or paid out automatically as the carriage is moved in and out. Loads may be picked up or discharged at any point along the line. Where sufficient inclination can be obtained in the main cable for the carriage to descend by gravity, and the loading and unloading are done at fixed points, the endless rope can be eliminated. The carriage, which is similar in construction to the carriage used in the endless-rope cableways, is arrested in its descent by a stop-block, which may be clamped to the main cable at any desired point, the speed of the descending carriage being controlled by a brake on the engine-drum.

For supporting the weight of the "fall" rope or hoisting rope, The Lidgerwood Mfg. Co., New York, uses "fall-rope" carriers spaced along a separate rope. The S. Flory Mfg. Co., Bangor, Pa., spaces them along the main track cable by sections of chains in loops. For details see makers' catalogs; also Peele, Mining Engineers' Handbook.

**SLACKLINE CABLEWAY.**—Fig. 3 shows three steps in the digging, conveying and elevating of material by a drag-line bucket (see p. 23-22) used with a slackline cableway. The bucket (Fig. 16) travels on an inclined track cable, one end of which is anchored. The other end is so rigged to the top of the mast that it can be tightened or slackened by the operator to vary its sag. One end of the hauling rope (load cable) leads to the bucket; the other end winds on a drum. The track cable spans the area served. When it is slack the bucket rests on the material to be dug, the hauling rope is wound in, the bucket digs its load and fills. The track cable is tightened, the bucket raised, and, according as the dump is at the high or low end, the carriage is pulled to or allowed to run to the dump. One man controls all operations. This type of plant is cheaply built and economically operated. It digs sand and gravel from pits and river beds, strips overburden and makes cuts and fills. By changing the position of the track cable anchorage and turning the mast it will dig a semi-circular pit. Fittings for slackline cableways and double drum hoists for operating them are made (see p. 23-81) by manufacturers [11], [50], [79].

**CABLE CRANES** are similar to suspension cableways, but by having one or both end towers movable they serve a greatly increased area. They are used in building canals, dams, locks and to serve large storage areas. In American practice (1936), work of this kind usually is done by power shovels (locomotive or crawler cranes) or slackline cableways, or combinations of them, with drag scrapers.

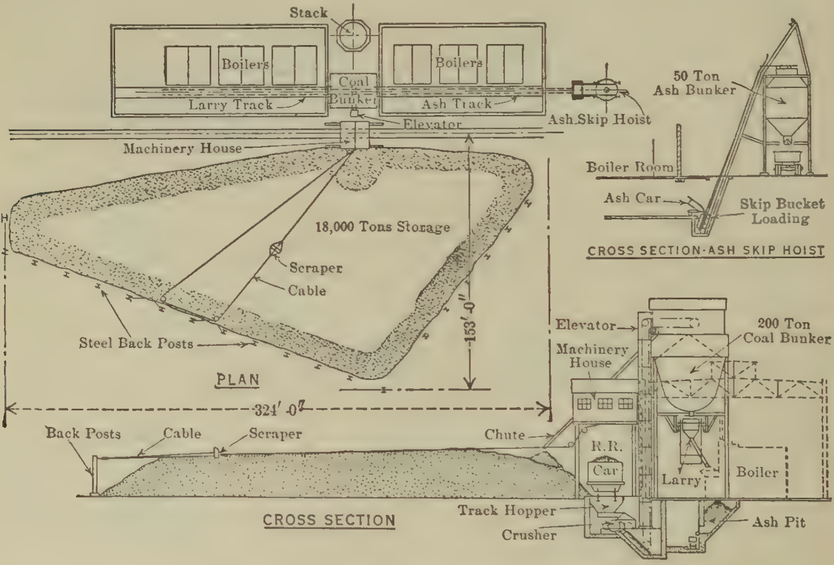


Fig. 4. Power Drag Scraper System

**POWER DRAG SCRAPER SYSTEM OF STORAGE.**—Fig. 4 shows elements of the system in a plant receiving coal by rail. The coal handling system crushes, elevates and delivers coal to the boiler-house, or forms a small pile near the railroad track. Two ropes run across the storage from a double-drum winding machine through tail blocks fastened to back posts. They are hitched to the front and back of an open end steel box, the scraper. Faced one way the scraper drags coal from the starting pile into storage; faced the other way it drags coal back to the track hopper. If the coal is frozen it goes to the crusher, otherwise the crusher is by-passed.

In small plants, tail blocks are hooked to tail posts, which are short steel columns in concrete piers. They may be hitched to a bridle cable stretched between adjacent posts. In large plants, back posts may be mounted on a car on a standard-gage track, and counterweighted to resist pull of the scraper rope. For high piles the tail block may be carried by a steel tower, 20 or 30 ft. high, on a broad flat car on wide-gage tracks. In one plant (Beaumont) the tail sheave is mounted on a caterpillar tractor which can travel anywhere on the storage lot and form a pile of any size or shape.

Advantages claimed for this system are: 1. Storage area can be any shape or size up to 900 ft. scraper travel. 2. Simple machinery, low first cost, cheap repairs, one-man operation. 3. Low fire risk in stored coal; ability to reach fire easily should it occur. 4. Wide range of economical handling capacities up to 1000 tons per hr.

Dragline scraper systems are built (see p. 23-81) by manufacturers [11], [50], [79]. Fig. 5

shows a Sauerman scraper; smallest size, $1/3$ cu. yd.; largest size, 12 cu. yd. Small drag scrapers for mines, tunnels, quarries are made by manufacturers [42], [86].

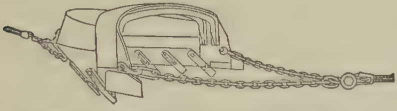

Fig. 5. Dragline Excavating Scraper

Fig. 6 shows a combination slackline cableway and dragline scraper system used in digging a canal in Russia and disposing of excavated material. All 3 towers are mounted on wheeled trucks running parallel to the canal. This combination has a higher capacity than could be obtained with a cable crane (see p. 23-16) spanning the whole width of the plant.

**Drag Scrapers in Cargo Boats.**—A number of self unloading boats on the Great Lakes and in coastwise service carrying bulk cargoes have a belt conveyor on a boom which can be slung to either side to discharge cargo ashore. See Fig. 7. Conveyor on the boom is fed from an inclined conveyor from the hold of the boat. There are several ways to take material from the hold and deliver it to the inclined conveyor. Some boats have two belt conveyors, others two apron conveyors, in tunnels extending the length of the cargo hold. Another method, patented by L. D. Smith, Sturgeon Bay, Wis., uses a pair of drag scrapers, each operated by its own double-drum winding machine, in two tunnels with smooth steel floors. Material flows into the tunnels through side openings. Along the top of each tunnel is an I-beam trolley track. The haulage cable is hitched to the open end of the scraper, Fig. 5; the pull-back cable for each scraper runs through a small tunnel, around end sheaves, over a trolley sheave hung from the I-beam, thence to the back of the scraper. The scrapers drop material into a hopper over the inclined conveyor. On the back pull the scraper is lifted up to the trolley, passes over material which has flowed into the tunnel, back to the starting point. Unloading capacities are 750 to 2000 tons per hr. Small scrapers are 4 cu. yd. capacity; large ones, 12 cu. yd. This system has been applied to tow barges with electric motors for operating the winding drums, but without generating plant. Power cables are run from the dock for unloading.

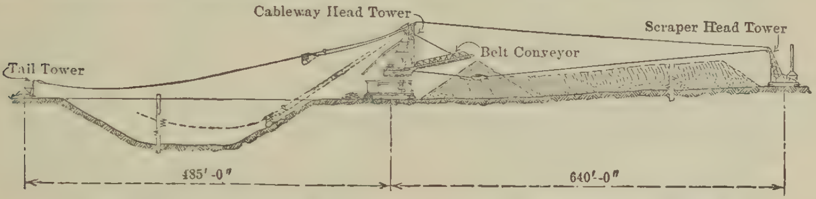

Fig. 6. Combination Slackline Cableway and Drag Line Scraper System

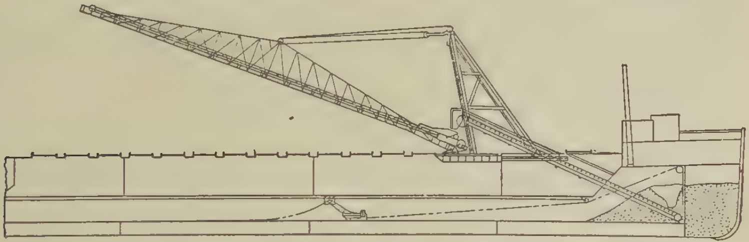

Fig. 7. Drag Line Scraper and Belt Conveyor System for Cargo Unloading

Boat unloading machinery with belt conveyors or apron conveyors in the tunnel is made by manufacturers [50], [77], [85] listed on p. 23-81.

## 2. LOCOMOTIVE CRANES

**LOCOMOTIVE CRANES,** Fig. 8, consist of a lower frame fitted with 4 or 8 wheels for use on track, and a rotating upper frame carrying the power plant and operating machinery. A boom, hinged to the upper frame, can be raised or lowered to handle loads at various radii. The crane will act as a portable hoisting engine, a swinging derrick, a grab bucket unloader or a switching engine. It will handle a lifting magnet, scoop shovel, dragline scraper or pile driver. Locomotive cranes with (usually) 8 wheels find widest application around industrial plants served by tracks. Besides lifting loads by hook block, they handle pig iron and scrap with a magnet, and shift cars.

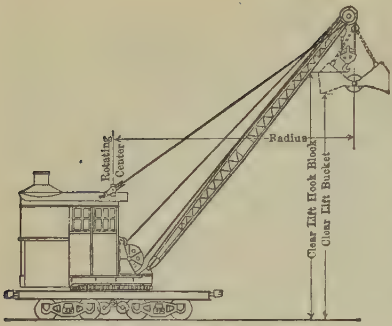

FIG. 8. Locomotive Crane

Steam-operated cranes require a boiler, fuel tank and water tank. Usually a licensed engineer is required to run the boiler. Many later cranes have gasoline or Diesel engines, which require less space, can be started or shut-down instantly, and have lower standby expense.

**Crawler Cranes** have, instead of wheels, a pair of treads made of steel plates linked together and driven by sprocket wheels. The weight is carried by a row of rollers on the lower frame. The width of tread plates and length of assembly make the unit bearing pressure so low that the crane can travel on soft, rough or uneven ground, and it requires no track or mats. Fig. 9 shows a machine built by Harnischfeger Corp., Milwaukee, Wis.

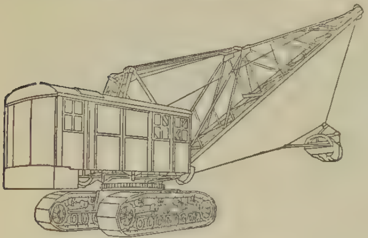

FIG. 9. Crawler Crane

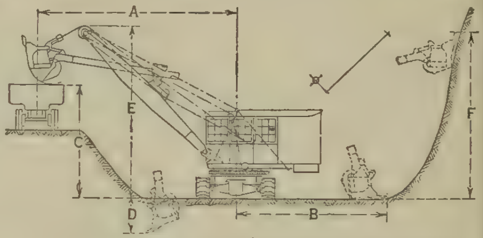

FIG. 10. Link-Belt Crawler Shovel (See Table 2)

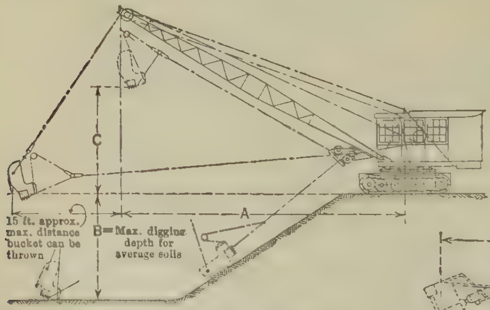
Crawler cranes as made by several companies are fitted with digging shovels, dragline buckets, trench hoes, skimmer buckets, etc. and can be converted easily from one to the other. The following information is from Link-Belt Co., Chicago:



C
A
15 ft. approx. max. distance bucket can be thrown
B=Max. digging depth for average soils

FIG. 11. Dragline Crawler (See Table 3)

**The Shovel,** Fig. 10 is for general excavating, digging from the bank, handling blasted rock and for grading, including shallow cuts below grade. Its particular field is making cuts into and through banks, loading blasted rock on cars or trucks, where the machine stands in the hole or at base of the excavation. It can be used on loose piled materials, but if reach is long or lift high a grab bucket often works better. Table 2 gives range of work for two sizes of machines.

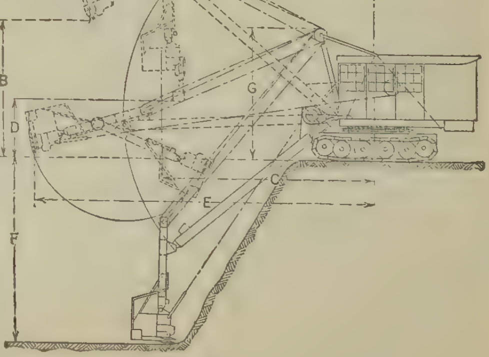


FIG. 12. Trench Hoe (See Table 4)

**The Dragline,** Fig. 11, is for removing overburden, digging under water, cutting wide or deep trenches, and where it is necessary to work above material handled. Dragline excavators work outside the hole, and when fitted with long booms can cover a large area, pile material high, and load cars some distance away. The dragline bucket is not so well suited to side cutting as the trench hoe. Table 3 shows the range of work for two sizes of dragline excavators. For dragline buckets, see Table 5.

**The Trench Hoe,** Fig. 12, is used to dig trenches up to 12 ft. wide and 20 ft. deep in earth that can be cut and which will not cave in. It is faster than the dragline, can be more accurately controlled and will cut a greater length of trench in a given time. Table 4 shows the range of work for two sizes.

**The Skimmer Bucket** is a form of shovel, comprising an open-end box armed with teeth. It travels back and forth on the underside of the crane boom and is used for grading, leveling, tearing up old pavements, etc.

Locomotive and crawler cranes with hoisting capacities up to 15,000 lb. at 40 ft.

### Table 2.—Dimensions and Capacities of Crawler Shovels

(Link-Belt Co., Chicago)

| Clearance Dimensions (See Fig. 10) | | | | |
|---|---|---|---|---|
| Dimension | Std. Lift Shovel, 20 ft. Boom, 15 ft. Stick | | High Lift Shovel, 35 ft. Boom, 21 ft. Stick | |
| | 40° Boom Angle | 60° Boom Angle | 40° Boom Angle | 60° Boom Angle |

| Size of bucket, cu. yd | 1–1 1/4 | 2–2 1/2 |

radius or with shovel capacity up to 3 cu. yd. are made (see p. 23–81) by [14], [39], [41], [50], [63], [64], [66]. Smaller cranes mounted on wide faced wheels or crawler treads with shovels of less than 1 cu. yd. are made for road builders and contractors by [16], [60], [87], and others. Some of these cranes cannot swing a full circle. Large excavators with shovel capacity of 4, 6, 9 cu. yd. are made by [15], [53], [67].

For a comparison of these large excavators with the chain and bucket ladder excavators used in Germany, see *Fördertechnik*, Oct. 26, 1928, May 8, 1931, Aug. 26, 1932.

**STORAGE SYSTEMS USING LOCOMOTIVE CRANES,** Fig. 13, shows a system of storing coal in semi-circular piles. Drop-bottom cars discharge to a central pit around which as a center are broad gage tracks for a long-boom crane. In large plants, working radius is 100 ft. The grab bucket has a capacity of 1 to 4 tons of coal which it digs from the pit and drops on the pile; in reclaiming, it digs from the pile and drops into cars. With coal piled 25 ft. deep a crane of 100 ft. radius will store 70,000 tons in a full circle with crane tracks covered. By continuing the tracks into more loops successive storage piles can be formed by one crane. The handling capacity, depending on size of bucket, is from 100 to 250 tons per hr.

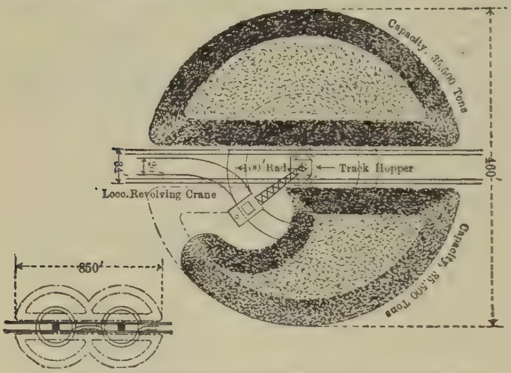

FIG. 13. Semi-circular Pile System of Coal Storage

Locomotive shovel cranes and crawler shovels are used with belt conveyors to remove excavated material, or to build levees. Dragline cranes, feeding a system of belt conveyors in tandem, are used in building levees along the Mississippi River. In 1929, over 6,000,000 cu. yd. were dug from a hill in the middle of Seattle, Wash., by crawler shovels, dumped into feed hoppers, thence to belt conveyors, some of them portable, and carried 3000 ft. for disposal. For the system used in building the Grand Coulee dam see *Engg. News-Record*, Aug. 1, 1935.

## 3. GRAB BUCKETS

**GRAB BUCKETS.**—Most rope-operated grab buckets, clam-shell buckets or orange-peel buckets work on the same principle, *viz.*, an upper head, and movable, relative to it, a lower head. The holding line, attached to the upper head, sustains the weight of the bucket when it opens. The lower head is connected to the bowl of the bucket and the closing line, so that when this line slacks the bucket opens. When it is pulled the bucket closes. Various styles of bucket differ in the manner of reeving closing line through sheaves or around a drum (power wheel) or of attaching it to arms or a crosshead so that pulling the closing line will cause the digging edges of the bowl to dig material and fill the bucket. See Fig. 14. Very heavy buckets may be operated with two holding and two closing lines to reduce size of rope, sheaves and drum. Fig. 15 is a diagram of two holding lines run from drum $H$ and clipped to an equalizer lever at the top of the bucket. The closing line runs from drum $C$, around sheaves $U$ and $L$ in the bucket, thence to an anchorage or back to the drum. This is the "fleeting through" method of reeving. If the crane handles a hook block or buckets of different sizes, the bucket is readily detachable if the two closing lines in the bucket are dead-ended, instead of being in one length.

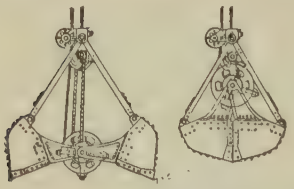

FIG. 14. Grab Bucket

The following is the cycle of operation of any rope-operated bucket: Assume bucket to be in upper position, Fig. 15, empty and closed; the weight is on the closing line. Drum $C$ turns to lower bucket; drum $H$ pays out holding line at the same rate of travel. As the bucket approaches material to be dug, $H$ is braked, $C$ pays out closing line, the weight of the parts $L$ pushes hinge of the bucket down, the halves open and the bucket is ready to bite. Both lines then are let go, and the bucket drops on the material. With holding line slack, the weight of the bucket resting on its digging lips, the closing line is pulled in; upper head *B* sinks, bucket closes, digs and fills. To raise bucket, *C* turns to pull in closing line, which now takes the weight; *H* pulls in the holding line. If the loaded bucket hangs from a trolley or carriage both drums are braked while the carriage moves. To lower the loaded bucket, both drums, under brake control, pay out line. To open the bucket, *H* is braked or stopped, *C* pays out closing line, lower head *A* sinks, and bucket opens. In its traverse back to the loading point, both drums are braked and the bucket stays open.

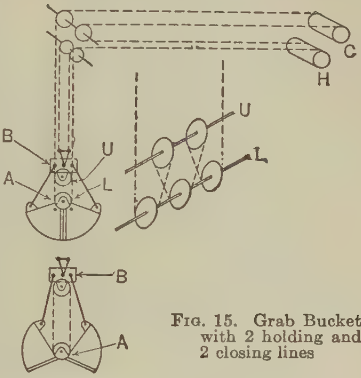

Fig. 15. Grab Bucket with 2 holding and 2 closing lines

The choice of a grab bucket depends chiefly on the material to be dug. Buckets with half-round bowls, Fig. 14, will dig loose free-flowing material and coal that is not too lumpy. To dig material that is lumpy or packed hard, the open bucket should have its digging edges in position to penetrate the material and not skid over it.

Digging buckets are made (see p. 23–81) by manufacturers [12], [40], [41], [92]. Table 5 shows heavy duty buckets made by Blaw-Knox Co., Pittsburgh, Pa. Similar buckets up to 7 cu. yd. size are made to handle quarry rock, blast furnace slag and other difficult materials. Buckets of special shapes are made to rehandle stone from gondola cars, ores from the hold of steamers, and to excavate under water.

Orange-peel buckets made by Hayward Co. and others have a hemispherical bowl divided into sections fitted with digging points. Holding, opening and closing is the same

**A* = No weights added; *B*, *C* = Digging capacity attained by adding weight to bucket; *T* = digging teeth required.

† Similar buckets to handle quarry rock, blast furnace slag, etc., are made in sizes up to 7 cu. yd. capacity.

**Table 6.—Weights and Dimensions of Single-line Buckets**

(G. H. Williams Co., Erie, Pa.)

| Capacity, cu. yd. | Approx. Weight, lb. | Overall Dimensions | | | | |
|---|---|---|---|---|---|---|
| | | Height, Closed | Height, Open | Length, Closed | Length, Open | Width |
| 1/2 | 2600 | 6′–3″ | 6′– 9″ | 4′– 6″ | 6′–9″ | 2′–9″ |
| 3/4 | 2800 | 6′–6″ | 6′–10″ | 5′– 0″ | 7′–3″ | 2′–9″ |
| 1 | 3400 | 7′–0″ | 8′– 0″ | 5′– 8″ | 7′–8″ | 3′–3″ |
| 1 1/4 | 3700 | 7′–3″ | 8′– 0″ | 5′– 8″ | 8′–2″ | 3′–6″ |
| 1 1/2 | 4800 | 8′–6″ | 9′– 3″ | 6′–10″ | 9′–3″ | 3′–9″ |

as in clam-shell buckets operated by two lines. They are made in sizes up to 1 1/2 cu. yd.; also in very small sizes that can be used in digging test-holes and holes for concrete piles.

Single-line buckets are made in the smaller sizes to rehandle loose material from cars or stock piles or for light excavating. They are hung on a single rope which runs from the hoist drum of a crane or derrick, through sheaves on the bucket to a closing-arm which pulls the halves of the bucket together. A latched arm holds bucket closed; it is tripped open by a hand line. It is not possible to lower a single-line bucket to a pile and then dump or discharge a part of its contents. Table 6 shows the usual sizes.

**Electric Motor Buckets.**—The Hayward electric motor bucket differs from all others. It uses an electric motor with a compact geared hoist in the upper head. Winding up a chain raises the lower head and closes the bucket; reversing the motor opens the bucket. A slip clutch prevents overload on the motor if the current is not cut off when the bucket is closed. Current is supplied through a flexible cable, which, when the travel is considerable, is automatically wound and unwound from a drum operated by an internal coiled spring, and with collector rings on the end of its axle. An electric controller, hand-operated, starts, stops, or reverses the motor to close, hold or open the bucket. This bucket can be hung on a single hoisting rope, or from the hook of a rope tackle used with a single drum, or from the hook of an ordinary hoist or crane.

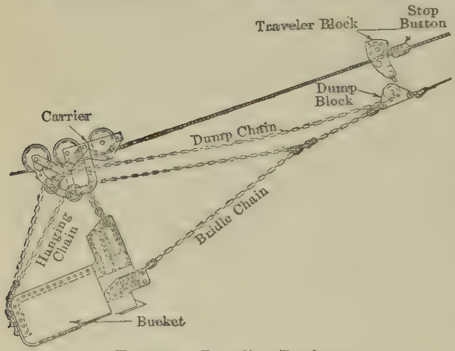

Fig. 16. Dragline Bucket

**DRAGLINE BUCKETS** are used with locomotive cranes, Fig. 11, or slackline cableways. The bucket is an open end box with a digging lip, with or without teeth. The dragline is hitched by a pair of chain bridles with clevis connections to front of bucket. When used with a locomotive crane, the bucket is pulled into dumping position by a line from one of the drums over the end of the boom, and hitched to the back end of bucket. In the slack cable system, the bucket, hung from the carriage, runs up the track cable with a traveler block, hits a stop button; further motion of the hauling rope pulls on the dump chain hitched to back of bucket. See Fig. 16. Dragline buckets are made (see p. 23–81) by manufacturers [12], [40], [79], [90], and others.

## 4. LIFTING MAGNETS

**LIFTING MAGNETS** are used with bridge cranes, monorail carriers, locomotive cranes and derricks to handle iron and steel of all kinds, sizes and shapes, hot or cold. In general the only labor needed is that of the crane man, who operates both crane motor and the magnet controllers. A magnet, in combination with a bridge crane, can pile steel higher and more compactly than any other means; cars can be unloaded more quickly and demurrage avoided; magnets will handle steel hot from the roll and will work under water.

A lifting magnet consists of a circular or rectangular cast-steel case enclosing copper coils, inner and outer pole shoes to form contact with the material lifted, and a non-magnetic shield to protect the coils from the material. Rectangular magnets have less lifting power than circular magnets. They lift only what they actually touch, but round magnets will operate through an air gap of 5 to 15 in. according to their size.

Fig. 17 is a cross-section of a round magnet made by Cutler-Hammer, Milwaukee,

**Table 7.—Average Lift, Pounds, for All-day Service of Lifting Magnets**
(Cutler-Hammer, Milwaukee, Wis.)

| Size of magnet, in. diam.* | 65 | 55 | 45 | 39 | 24 |
|---|---|---|---|---|---|
| Skull cracker balls | 40,000 | 30,000 | 24,000 | 18,000 | 6000 |
| Slabs | 60,000 | 50,000 | 35,000 | 20,000 | 6500 |
| Machine-cast pig from cars | 2,800 | 2,280 | 1,275 | 750 | 250 |
| Sand-cast pig from cars | 2,650 | 2,170 | 1,150 | 680 | 225 |
| Broken scrap | 1,800 | 1,300 | 1,000 | 600 | 200 |
| Cast-iron borings | 2,300 | 1,500 | 1,100 | 600 | 200 |
| Steel turnings | 1,100 | 750 | 450 | 300 | 100 |
| Principal Uses | Large capacity; heavy duty | Open-hearth plants; steel mills | Gen. work; larger cap'y with loco. cranes | Pig. iron; scrap; med. cap'y with loco. cranes | Light finished parts; pipe; castings |

* Round magnets 18 in., 12 in., 7 in., 5 in. diam., also are made.

and Table 7 gives capacity per lift for different kinds of service for average 10 hr. steady work. If service is not continuous, the coils run cooler and the lifting capacity is greater.

Round magnets and magnets of other shapes are also made by Ohio Elec. Mfg. Co., Cleveland. Fig. 18 shows 3 rectangular magnets hung from a spreader beam for lifting long plates.

To provide direct current needed for a magnet, locomotive cranes are fitted with a generating set in the cab. On alternating-current bridge cranes, a motor-generator set on a platform over the operator's cage supplies direct current. The trolley has a cable winding drum for taking up or paying out electric cable to the magnet.

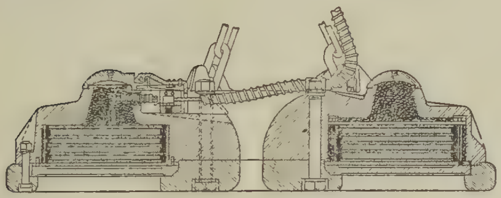

Fig. 17. Lifting Magnet

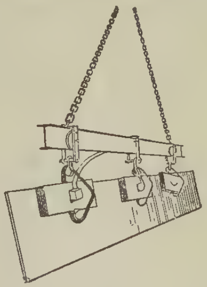

Fig. 18. Lifting Magnet, Handling Long Plates

Round magnets often are hung over a belt conveyor to remove stray iron from coal, foundry sand, etc., carried on the belt. The diameter of the magnet should be $1/3$ larger than the belt width, and it should not be higher above the belt than $1/4$ the belt width. Belt speed should not exceed 450 ft. per min.

## CRANES AND DERRICKS

A hoist is a machine for raising and lowering loads. A crane is a hoist or number of hoists so mounted as to move loads both vertically and in other directions.

**SAFETY STANDARDS FOR CRANES, DERRICKS AND HOISTS.**—The safety code sponsored by the A.S.M.E. and the A.S.A. (1933) defines terms, states requirements of design and construction and gives rules to promote safety in operating.

Cranes generally are tested by their makers with a load 25% greater than the load for which they are rated.

### 1. TYPES OF CRANES

Cranes which lift and swing the load are pillar cranes, jib cranes in various forms, derricks, rotary bridge cranes, locomotive cranes. Cranes which lift the load and travel with it comprise many forms of bridge and gantry cranes.

**A PILLAR CRANE** consists of a stiff self-supported column, turning on a vertical axis and fitted with an inclined boom, the end of which carries the load. The boom swings in a full circle on ball or roller bearings. Hoisting is by hand power winch on the column. Fig. 1 shows a type made in sizes of 2 to 20 tons; working radius 12, 15 or 20 ft.

**Pillar Jib Cranes** have a trolley traveling on a horizontal boom to carry the load. The hoist is hand or power; the trolley usually is moved by hand. The jib may be two channels or a single I-beam for chain, electric, or air hoist. See Fig. 2.

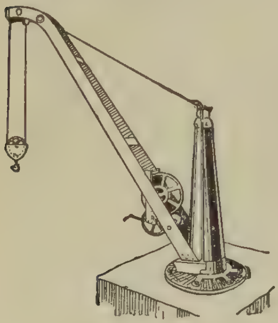

Fig. 1. Pillar Crane

## Jib Cranes

**TOP-SUPPORTED JIB CRANES** require the top of the column to be braced to a wall or ceiling, or by guy-ropes or struts. They include yard derricks, foundry cranes and sidewall cranes for machine shops. Fig. 3 shows one with separate hand winches for hoist and traverse. Jib cranes sometimes are made with single I-beam jib for hoists hung from 4-wheel trolleys as auxiliaries to traveling bridge cranes.

**PORTABLE JIB CRANES** can be made to serve different areas of shop floor as needed, by fitting building columns with socket connections to fit loose-pin connections on the crane mast.

**BRACKET JIB CRANES** have a horizontal jib hinged to a wall bracket by a vertical pin, and stayed by a rod hinged to an upper bracket. The form shown in Fig. 4 has an I-beam jib for a trolley, from which hangs a hand or power hoist. Bracket jib cranes also are made with built-up girder rail jibs for Cleveland tramrail or American monorail. See p. 23–44. The ends of the special rail on the jib can be fitted with interlocks to engage with fixed tramrail. Trolleys on the jib thus also may run on tramrails radiating from the bracket crane, and serve a large area. To serve trolley tracks running through a doorway, Richards-Wilcox Co., Aurora, Ill., and others, make bracket jib cranes hinged to lie flat against the wall and allow the door to close.

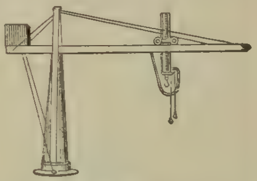

Fig. 2. Pillar Jib Crane

**WALKING CRANES** and **Traveling Wall Cranes** are jib cranes mounted for longitudinal travel; the first runs on a track on the shop floor with an upper rail on the wall or building columns to take the thrust at the top of the mast. The wall crane, Fig. 5, (Niles-Bement-Pond Co., New York) has an upper and a lower thrust track on which run flat-faced rollers, while the vertical load is taken on a separate rail mounted on wall brackets. The thrust load is much greater than the dead load when the trolley is at the extreme end of the crane. Such cranes act as auxiliaries to shop bridge cranes in serving long lines of machine tools or in handling riveters on long structural steel work.

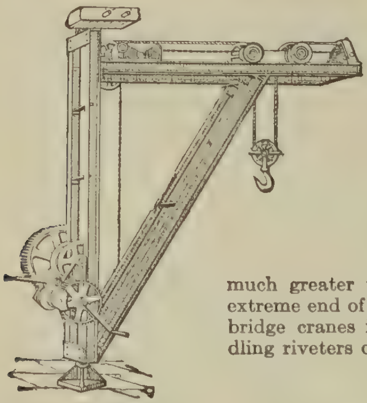

Fig. 3. Top Supported Jib Crane

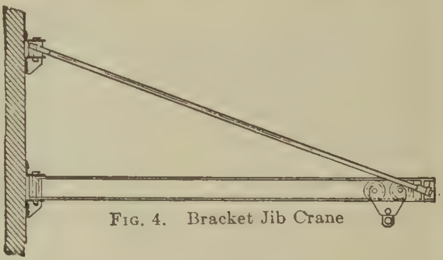

Fig. 4. Bracket Jib Crane

## Derricks

**GUY DERRICKS** have a mast, with a step and vertical pivot pin, at the base, a boom hinged to the foot of the mast, whose inclination can be varied by rope tackle joining tops of boom and mast. A pivot pin on top of the mast fits a cap to which guy ropes are attached. For hand operation, a double-drum winch is mounted at the base of the mast for hoisting and luffing respectively. If angle of boom is not often changed, a single-drum winch will suffice, luffing being by a hand line hitched to the mast. Fig. 6 shows a guy derrick used in quarries and by contractors in bridge and building construction. It is operated by steam or power hoist with two hoisting drums for load and luffing, and a pair of swinging drums. Ropes from the latter lead to opposite sides of a bullwheel, on the foot of the mast, to swing mast and boom. The luffing rope runs to foot of mast, to masthead, thence to tackle between masthead and top of boom. The hoisting rope follows a similar path, and runs through sheaves on the boom to the suspended load. The stress in the hoisting line (fall rope) can be taken from Table 4, p. 23–04. Stress in boom-hoist tackle increases as boom is lowered. Hoisting rope is generally 6 × 19 steel wire rope; boom hoist line is the same, but with more parts in the tackle. Stresses in guy lines can be calculated from their arrangement around the mast with respect to the position of the load and also with respect to the angle they make with the horizontal. For other points on derrick design, see Amer. Cable Co. Wire Rope Users' Handbook. Contractors' derricks often are made of steel for safety, and in sections for ease in handling.

Fig. 5. Traveling Wall Crane

**STIFF-LEG DERRICKS** are used where it is not feasible to run guy ropes, or where derrick must be shifted often. See Fig. 7. Struts from masthead, inclined at 45°, are framed, or hinged, to two sills set on the ground at 90°, meeting under the step of the mast. The boom can swing 270°. Sills can be bolted to foundations or held down by weights.

**JINNIWINK DERRICKS** are similar to stiff-leg derricks. An A-frame replaces the mast, and with its back strut is mounted on a T-shaped frame acting as a base. The boom, hinged to the base frame, is adjustable for angle. These derricks, light and easily set up, are used by building contractors.

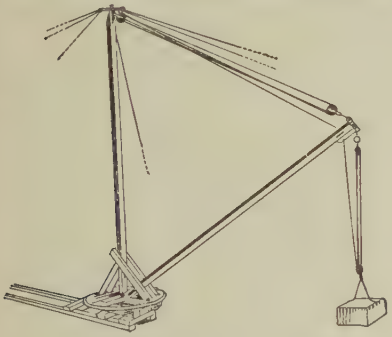

Fig. 6. Guy Derrick

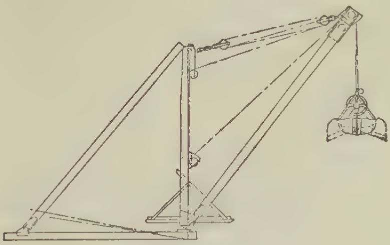

Fig. 7. Stiff-leg Derrick

**TOWER DERRICKS** consist of a square tower of wood or steel with footings for booms on one or more corner posts. They are used in building construction, booms being shifted higher on the posts as the building goes up. A steel tower derrick with a revolving pivoted counterweighted 50-ft. boom is used in building construction in Germany. It will lift 1 ton with boom horizontal; maximum height of lift with boom luffed, 100 ft. The tower rests on a wheeled platform, and has 3 small electric winches, controlled by a man on the platform.

The concrete distributing apparatus made by Insley Mfg. Co., Indianapolis, Ind., is a modified mast and tower derrick. The mast hoist has a framed steel mast, about 20 in. square, made in 20-ft. sections with bolted end connections and guy attachments. It has guides for a dump bucket which discharges into a receiving hopper adjustable in height on the mast, from which chutes distribute concrete. The upper end of the chute is a boom, guyed from the mast head. Extensions of the chute hang from trolleys on a chute-extension cable which spans the area over which concrete is distributed. Fig. 8 shows a 60-ft. mast with a 40-ft. boom chute, served by a 1-yd. hoist bucket. Larger plants have steel or wood guyed towers, with one or two hoist buckets. Masts and towers for this system of distributing concrete have been designed and standardized for rapid and easy erection.

Complete steel derricks or fittings for wooden derricks are made by manufacturers [3], [21], [49], [52] (see p. 23-81) and by makers of steam, electric or gasoline hoists and of equipment for contractors.

## Traveling Cranes

**TRAVELING BRIDGE CRANES.**—Makers of tramrail equipment (see p. 23–81) list and illustrate in their bulletins a wide variety of light cranes for 2 tons or less load. Table 1 classifies Cleveland tramrail bridge cranes; similar cranes are made for American monorail. These light cranes are notable for several reasons: 1. End trucks have equalizer levers and swivel wheels; wheel flanges do not bind on the rail. 2. Structure is light; wheels have ball bearings; crane is easy to move. 3. The light construction of bridge, flexible mounting of the wheels, and absence of a squaring-shaft permit cranes to be hung from 3 runways if bridge is longer than 30 or 35 ft. By using 3 runways weight of the bridge can be kept so low that a 50-ton crane can be moved by pushing or pulling the load, and there is no danger of pinching or binding the runway. 4. Most types can be fitted with interlocks to register bridge rails with fixed tramrail, so that hoists, carriers and trailers can travel on or off crane bridge. 5. Electrical conductors and mountings, control and accessories are well standardized. See Fig. 9.

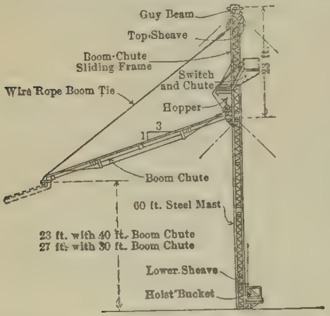

Fig. 8. Tower Derrick and Boom Chute

Other bridge cranes, for loads up to 5 tons and for spans under 30 ft., are made of single I-beam spans with trolley hoists hung from lower flanges. The bridge travel of these cranes is generally by hand-chain hung from a chain-wheel on a squaring shaft that drives truck wheels at each end of the span. For loads over 3 tons, it is better to have a gear reduction between chain gear and squaring shafts.

**Double I-beam Cranes** are used for loads up to 20 tons and for spans of 20 to 50 ft. The trolley runs on top of the girders. The hoist rope is wound on a drum which may be geared to hoist light loads at faster speed than heavy loads. With double I-beams, the load hook can go between the beams, and for a given lift, the building need not be so high as it would be if trolleys were hung below the beam. Some cranes have two trolleys for handling long or heavy pieces.

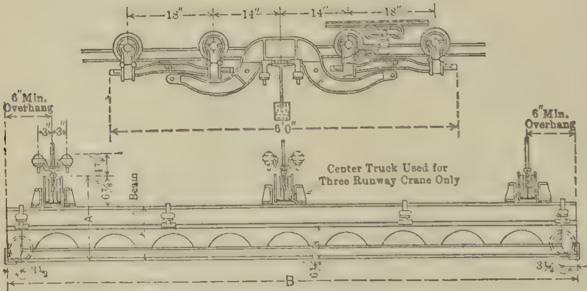

Fig. 9. Cleveland Tramrail Crane

The hand-power cranes mentioned are for what crane builders call class D, *i.e.*, very intermittent, service. If hand operation is too slow, I-beam cranes can be fitted with one or two motors (class C service), or with three motors for class B service, which means the ordinary work of a crane in shops, foundries, yards, etc., where the crane is busy 8 or 10 hr. and adjustments, inspections and repairs can be made in idle time.

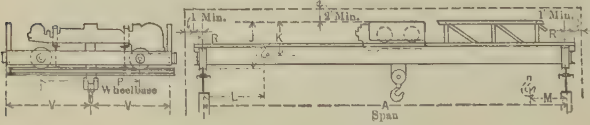

Fig. 10. Light-duty Bridge Crane

**A 3-motor Bridge Crane** for class B service is shown in Fig. 10 and Table 2. The bridge is made of two I-beams to carry the load, with two light lattice-girders to stiffen the frame and to help carry the travel machinery. The bridge often can be shipped and erected as a unit. The trolley frame is a one-piece steel casting; the double-flanged

**Table 1.—Cleveland Tramrail Bridge Cranes**
(Cleveland Crane & Engg. Co., Wickliffe, O.)

| Type | Bridges Propelled by Hand (Pull or Push Load) |
|---|---|
| CH | For any Cleveland carrier or hoist, hand or electric up to 2 tons capacity; 2 runways for bridge lengths up to 30 ft.; 30 to 50 ft. 3 runways. |
| CHL | For any Cleveland carrier or hoist, hand or electric, up to 2 tons capacity; 2 runways for bridge lengths up to 30 ft.; low headroom. |
| DGH | Double girder bridge; trolley hoist on top. Capacities up to 1 ton; 2 runways for bridge lengths up to 30 ft.; low headroom. |
| | Bridges Propelled by 2 or 3 Motors |
| UCE | For any Cleveland carrier or hoist, hand or electric up to 2 tons capacity, 2 runways for bridge length up to 30 ft.; for 30 to 50 ft. 3 runways. |
| DGE | Double girder bridge; hand pushed trolley; capacities up to 2 tons; 2 runways for bridge lengths up to 30 ft.; low headroom. |
| DGEE | Same as DGE except that trolley is motor-driven. |
| DGC | Like DGEE, but operator controls all motions from cab mounted on bridge. |

| 7 1/2 tons | 24 | 110 | 175 | 15 | 2 | 5 | 9/16 |
| 10 tons | 18 | 110 | 175 | 15 | 2 | 5 | 9/16 |

trolley wheels run on flat bars welded to top flanges of the girder beam. These and similar cranes are made (see p. 23–81) by manufacturers [28], [41], [54], [61], [76], [80], [91].

Cranes for class A service work 24 hr. per day in steel mills, cement mills and foundries, or on heavy hoist and grab bucket or magnet work, where interruption of service is serious. Speeds of hoists, trolley and travel often are higher than for cranes in lighter service; motors are larger; parts are designed with a higher factor of safety and with more regard to access to working parts and certainty of lubrication. Such cranes are made by some of the companies noted above, also by (see p. 23–81) manufacturers [1], [20], [39], [59], [81]. Fig. 12 and Table 3 show cranes for heavy service. Cranes made by various makers do not differ much in essential dimensions.

**AUXILIARY HOISTS FOR CRANES.**—The dimensions *P* and *G* in Table 3 for cranes over 10 tons refer to position of hook of the auxiliary hoist, which is used for rapid hoisting of loads lighter than those for which the crane is designed. For this duty the trolley carries two motors, each with its own set of drums and gearing. One set is for the main hoist of the rated capacity of the crane; the other is for 3, 5 or 10 tons auxiliary capacity.

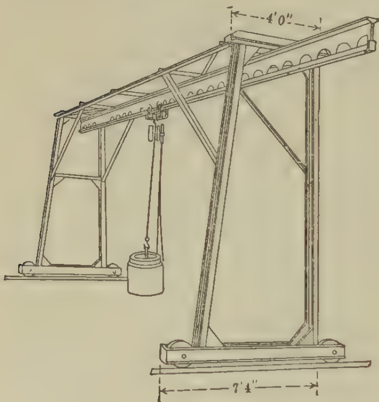

Fig. 11. Tramrail Gantry Crane

**CRANES FOR OPERATING GRAB BUCKETS** for handling coal at power plants, raw material and clinker at cement plants, unloading bulk material from cars, etc., have a trolley with two drums, one for closing line and one for holding line. The drums are mounted parallel to the bridge girders; each has its own motor, solenoid brake and reduction gearing. If the crane does miscellaneous hoisting and a bucket is used only occasionally, the trolley can be of the ordinary hoisting type, and the bucket of the single-line or one of the motor-driven types, to be put on the hook block when needed. See p. 23–20.

Grab bucket cranes are made by most builders of heavy type bridge or gantry cranes. Dimensions of trolley vary with weight and type of grab bucket and height of lift. Parts generally are of heavy construction, and precautions are taken to keep dust out of gears. All motions of crane and bucket are electrically controlled from the operator's cab, usually mounted on the trolley.

**TRENDS IN CRANE DESIGN.**—(*Trans.* A.S.M.E., 1928, MH–50–1) Modern cranes are characterized by less dead weight, by rolled beams instead of box girders, lighter motors, alloy steel parts, ball or roller bearings, heat-treated gears, gears enclosed for protection and running in oil baths, grease cups and intermittent oiling being avoided. Bridge cranes with structural parts of aluminum alloy are described in *Engg. News-Record*, Oct. 8, 1931. Advantages claimed are reduction of weight, less power for travel motions and no necessity of painting. Comment of *Fördertechnik* is to the effect that the percentage of weight saved would not be so great for German cranes as they are lighter than American cranes for the same service.

Cleveland Crane and Engg. Co. makes cranes in which end trucks, trolley frames and bridge girders are arc-welded and not riveted. Advantages claimed are greater rigidity and strength, less weight, faster acceleration, reduced maintenance.

**GANTRY CRANES.**—For loads up to 2 tons Cleveland tramrail can be fitted to two gantry legs. See Fig. 11. All wheels have ball bearings, and the structure, with load, can be moved by one man at either end pushing or pulling. For rapid or long travel the crane can be electrically propelled. These cranes can be used in shops as auxiliaries to traveling bridge cranes. Cleveland gantry cranes can be interlocked to register bridge rails with fixed tramrail so that hoists, carriers and trailers can move on and off the gantry bridge.

Gantry cranes of heavier type, Fig. 13, range in size from 5 to 250 tons, of any span. As regards construction, they are like bridge cranes built for hoist, bucket or magnet work, but have better protection from weather for operator and machinery. For travel motion, power is transmitted from a motor on the bridge through horizontal and vertical shafts to geared truck wheels at ground level. Truck should have brakes to prevent high winds moving the bridge. Such mechanical and electrical brakes are described in *Trans.* A.S.M.E., 1930, IS–52–4. If the crane serves a yard alongside a building it is sometimes convenient and economical to support one crane track on the building wall. The crane is then a *single-leg gantry.*

* To main hook.

Note: Cranes of 50 tons capacity and above, and of 60 ft. span and over usually are equipped with 8 truck wheels. On 10-ton crane with 3-ton auxiliary hoist, dimensions *B* and *F* are 3 in. greater. Wheel loads specified do not include impact.

Advantages of gantry cranes are: No expense for overhead runways; tracks can be extended or changed in position; no obstruction of yards by overhead track supports.

**Portal Cranes** (double-leg) or **semi-portal** cranes, single-leg, are similar to gantry cranes. They generally have a rotating crane, or a crane with luffing motion mounted on top of the structure to transfer freight from ship to wharf, or *vice versa.*

SPECIAL CRANES FOR STEEL WORK.—**Ladle cranes** are made up to 300 ton capacity to control all the motions of filling, transporting and pouring hot-metal ladles in open-hearth plants. They have two independent trolleys with a pair of girders for each. The main trolley travels on the outer girders and hoists the ladle; the auxiliary trolley travels on the inner girder and has two hoists to tilt the ladle one way or the other. To insure safety, the two hoist motors and two sets of hoisting machinery are geared together to prevent the ladle from tipping sidewise and spilling metal if one motor or set of gears should fail.

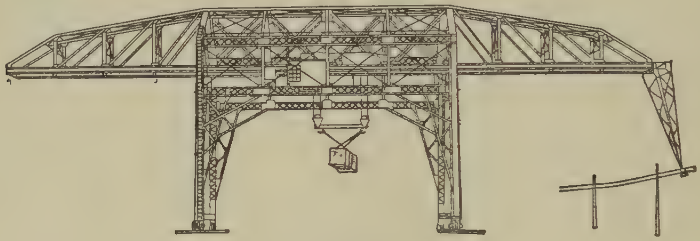

Fig. 13. 50-Ton Gantry Crane

**Ingot-stripping Cranes** are of several types. In one, a vertical arm suspended from a trolley carries jaws which seize the hooks of the ingot mold, while a screw-actuated plunger pushes the ingot from the mold. Some cranes carry auxiliary trolleys to handle stripped ingots. In rope-operated cranes, the hoist block carries tongs which lift the mold while a stationary ram pushes the ingot out.

**Soaking-pit Cranes** do all the work of handling ingots into and out of soaking pits. In one type, a trolley carries a guided vertical ram, gear-operated, with gripper jaws on the lower end. These have an automatic closing motion, suitable to ingots of different widths. The ram rotates on a vertical axis. This type requires high headroom. Rope-operated types require less headroom, have a shorter ram, and the guides are below the trolley (Alliance Machine Co., Alliance, O.).

**Crane-type Charging Machines** are made by Wellman Engg. Co., Cleveland. A vertical frame moves with the trolley and is braced against the under side of the bridge girders. It carries an arm that holds the charging box and turns it over when it has been pushed into the open-hearth furnace.

ELECTRICAL EQUIPMENT FOR OVERHEAD CRANES.—(From Crane Engineering by Whiting Corp., Harvey, Ill.) Alternating current generally is used for most cranes. More delicate control can be obtained than with direct current, especially for light loads. If both alternating and direct current are available, choose alternating; if only direct current, do not convert it to alternating, but use it.

**Motors.**—Slip-ring motors with wound rotors are preferable for crane service. Squirrel-cage induction motors may be used if delicate control is not required. Crane motors are rated for a given temperature rise in a stated operating time. For heavy service the Hp. rating is limited to a temperature rise of 40 to 50° C. in 60 to 90 min. operation. For intermediate or light service, a higher rating, based on 30 to 50 min., is permissible.

**Controllers.**—Drum-type controllers, with cast-grid resistance, are preferable for both direct and magnetic control. Arcing is relieved by blowout coils, and for protection, controller is completely enclosed. Controllers for operating from floor instead of from cab have a cable drum with spring return. Special controllers to give 90% reduction of full-load speed can be supplied for delicate control in foundry work.

**Switchboards.**—Main switch- and panel-boards are mounted in the rear of cab and totally enclosed. The switch may be locked in open position and it is impossible to open fuse box without opening main switch. Contactors for limit switches, magnets and magnetic control are accessibly located in the rear. Push buttons and master switches are in front near control levers. For heavy duty, cranes should have overload and low-voltage relays to protect all circuits. For regular service standard fuses generally are used.

**Crane Wiring** should conform to Underwriters' National Electric Code.

**Brakes.**—In alternating-current service, hoist motor has two brakes, one mechanical and one electrical, either of which will sustain full load. The principle of the mechanical brake is shown in Fig. 1, p. 23–37. The electric solenoid brake has a weighted plunger, which releases the brake shoes, and a wound coil to act against the weight and clamp the shoes to the drum on the motor shaft. Brake shoes are a composition of asbestos and graphite and are adjustable. Direct-current service uses dynamic braking. One or two solenoids are used to stop motor and hoist.

**Collectors and Conductors.**—Runway conductors are furnished by the crane purchaser. They should be spaced 8 to 10 in. vertically, and supported about every 20 ft. by insulated brackets. Wire conductors should be pulled tight by strain insulators at the ends.

**OPERATING SPEEDS OF CRANES.**—Table 2 shows motor sizes and operating speeds of shop cranes in intermittent service. For heavy-duty and 24-hr. service, heavier motors and higher speeds generally are used. High speeds of hoist and travel cannot be attained in short movements, because much of the time is used in accelerating and decelerating moving parts. See p. 23–32. In estimating capacity of a crane to hoist and transfer loads, allowance must be made for time thus lost. For short travel, as in transferring loads from car to adjacent storage, the allowance may be 25% or more.

**CRANE SUPPORTS.**—Running rails are furnished by the user; size is recommended by the maker for the particular service. They must be laid straight and at exact center to center distance. Track supports should be strong enough to carry maximum load close to one end of bridge, and stiff enough laterally to take the shock of sudden stops of the loaded crane trolley. Column connections and columns must be designed on a basis of maximum loads. It is well to consult crane builders before design of the building has gone too far.

**HOISTING ROPES** are cast-steel wire rope, usually 6 × 37; 6 × 19 and 8 × 19 also are used. Sheave and drum diameter should be (30 × rope diam.) See p. 6-34. For use of wire rope see p. 23-04.

## 2. POWER REQUIRED TO DRIVE CRANES

**POWER REQUIRED TO DRIVE CRANES.** (Adapted from Electric Crane Construction, by C. W. Hill, 1911.)—The current for hoisting is expended partly in lifting the load and partly in losses in the motor, the solenoid brake, the hoisting gearing and bearings and the friction and bending of the ropes on the drums and sheaves. As a rough average for shop cranes, these current expenditures may be 70% useful work and the losses 14%, 1%, 12%, and 3%, respectively, of the total current furnished. The size of the motor is determined by the torque required to lift the load plus the torque necessary to bring the load and all the rotating mechanism up to speed in the time allowed by the designer for the hoist to attain its full speed. The overload torque required for acceleration to a speed $v$ in $t$ seconds varies as $1/t$, and that factor, rather than the torque for direct lift, determines the size of the motor in all hoists except very slow ones. In a typical crane hoist, Fig. 14, the effect of the acceleration of all the moving parts on the torque of the motor can be obtained by calculating the weight and radius of gyration of the moving parts at the drum shaft and on all other rotating shafts, and then finding an equivalent weight which at the center of gyration of the motor armature, will produce the same energy effect. If $W$, $w$, $R$, $r$, $N$, $n$ are the weights of revolving parts, radii of gyration, and numbers of revolutions of two geared shafts respectively, then

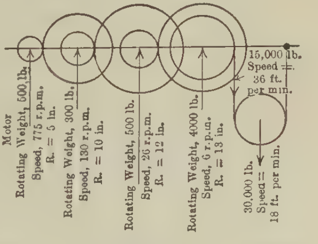

FIG. 14. Diagram of Crane Hoists Speeds

$$WR^2N^2 = wr^2 n^2, \text{ and } w = WR^2N^2/r^2 n^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad [1]$$

The force necessary to accelerate a weight $w$ to a velocity $v$ in time $t$ is $(w/g)(v/t)$. The duty required of the hoist motor in Fig. 14 can be calculated as follows:

1. Assumed load on hook, 30,000 lb. on four $^3/_4$-in. ropes; load on drum, 15,000 lb.
2. Drums, 23 in. diam., = 6 ft. circumference.
3. Speed of hoist rope, 36 ft. per min. = 0.6 ft. per sec.
4. Time to attain full speed, 5 sec.
5. Speed of motor, 775 r.p.m.; weight of revolving parts, 500 lb.; radius of gyration, 5 in.; velocity at center of gyration, 2029 ft. per min. = 33.8 ft. per sec.
6. Speed of first countershaft, 130 r.p.m.; weight of revolving parts, 300 lb.; radius of gyration, 10 in.; equivalent weight at center of gyration of armature is

$$300 \times 10^2 \times 130^2/5^2 \times 775^2 = 33.76, \text{ say } 33.8 \text{ lb.}$$

7. Speed of second shaft = 26 r.p.m.; weight of parts, 500 lb.; radius = 12 in.; equivalent weight at center of gyration of armature = $500 \times 12^2 \times 26^2/5^2 \times 775^2 = 3.2$ lb.

8. Speed of drum shaft 6 r.p.m.; weight, 4000 lb.; radius of gyration, 13 in. equivalent weight at center of gyration of armature $= 4000 \times 13^2 \times 6^2/5^2 \times 775^2 = 1.6$ lb.

9. Speed of weight and rope, 36 ft. per min.; equivalent weight at armature is

$$15{,}000 \times 36^2/2029^2 = 4.7 \text{ lb.}$$

10. Total equivalent weight at center of gyration of armature $= 500 + 43.3 = 543.3$ lb., say 543 lb.

11. Force at armature to lift weight $= 15{,}000 \times (36/2029) = 266$ lb. Add $^1/_6$ of this $= 44$, approximately, for losses in gearing and ropes; $266 + 44 = 310$ lb.

12. Force at armature to accelerate all moving parts in 5 sec. is

$$(w/g)(v/t) = (543/32.2) \times (33.8/5) = 114 \text{ lb.} + {}^1/_6 \text{ for losses} = 133 \text{ lb.}$$

13. Ratio of (12) to (11) $= 133 \div 310 = 0.429$, *i.e.*, overload during period of acceleration is 43% for 5 seconds.

14. Horsepower for lift only $= 310 \times (2029/33{,}000) = 19.06$ Hp.

15. Horsepower for lift and acceleration is $(310 + 133)(2029/33{,}000) = 27.23$ Hp.

In a similar way, the power required to travel the bridge may be investigated.

16. Dead weight of crane assumed 75,000 lb.; load 30,000 lb.; total 105,000 lb.

17. Assumed coefficient of rolling friction, 30 lb. per ton; tractive effort at truck wheels $= (105{,}000/2000) \times 30 = 1575$ lb.

18. Speed of travel, 300 ft. per min. = 5 ft. per sec.

19. Time to attain full speed of travel, 15 sec.

20. Speed of armature, 775 r.p.m.; weight of revolving parts, 500 lb.; radius of gyration, 5 in.; velocity at center of gyration = 2029 ft. per min. = 33.8 ft. per sec.

21. Equivalent weight at center of gyration of armature for revolving parts [like (6), (7), and (8)], assumed 100 lb.

22. Equivalent weight at center of gyration of armature for traveling load is

$$105{,}000 \times 5^2/33.8^2 = 2297 \text{ lb.}$$

23. Total equivalent weight at armature $= 500 + 100 + 2297 = 2897$ lb.

24. Force at armature to travel crane at 30 lb. per ton $= 1575 \times (5/33.8) = 233$ lb. $+ {}^1/_6$ for losses $= 272$ lb.

25. Force at armature to accelerate all moving parts in 15 sec. is

$$(w/g)(v/t) = 2897 \times 33.8/32.2 \times 15 = 202 \text{ lb.} + {}^1/_6 \text{ for losses} = 236 \text{ lb.}$$

26. Ratio of (25) to (24) $= 236 \div 272 = 0.87$, *i.e.*, overload during period of acceleration is 87% for 15 sec.

27. Horsepower for travel only $= 272 \times 2029/33{,}000 = 16.7$ Hp.

28. Horsepower for travel and acceleration $(272 + 236)2029/33{,}000 = 31.2$ Hp.

From these figures we see that while a 20-Hp. motor might do for the hoist, which approximately figures 19 Hp., and not be overtaxed by the overload of 50% for 5 sec., the travel, which figures 16.7 Hp., requires a larger excess of torque because the overload of 88% is exerted for 15 sec. The full power of the motor during that time amounts to 31.2 Hp., so that a 25-Hp. motor is advisable. It will at the same time take care of irregularities in the track and poor handling of the controller. From (25), it is apparent that if the time of acceleration were reduced to 7 $^1/_2$ sec. the horsepower for travel and acceleration would be over 45 Hp. Characteristic curves of motors published by the makers show the permissible relations of torque and time, and should be followed in the selection of sizes.

**PRACTICAL RULES.**—Builders of traveling electric cranes used in shops assume a hoisting efficiency of about 70%, which corresponds to 23,000 ft.-lb. per min. per Hp. of motor rating. For cranes used in steel mills, grab-bucket hoisting, etc., subjected to occasional overload and rough handling 20,000 ft.-lb. per min. per Hp. is used. The margin of 30% or 40% generally is considered sufficient to allow for acceleration and for electrical and mechanical losses, but for high hoisting speeds and quick acceleration, the forces due to acceleration should be calculated and allowance made for them.

For travel speeds not over 250 ft. per min. a rule used in practice is

$$\text{Motor Hp.} = 2\left[\left(W \times \frac{d}{D} \times 0.07 \times 1.07^n \times S\right) \div 33{,}000\right] \quad . \quad . \quad . \, [2]$$

where $W$ = weight of loaded crane, lb.; $d$ = diameter of truck axles, in.; $D$ = diameter of truck wheels, in.; 0.07 = coefficient of axle friction, and also is the loss at each cut gear reduction, including journal friction of countershaft; $n$ = number of gear reductions; $S$ = speed, ft. per min. The factor 2 covers overload due to acceleration, bad condition of crane track, "notching-up" controller too rapidly, etc. For greater safety against these adverse conditions, the factor sometimes is made 2 $^1/_2$. For speeds over 250 ft.

per min. and for quick acceleration the forces due to acceleration should be calculated and allowed for.

Crane Engineering, by Whiting Corp., Harvey, Ill., gives the following rules: Hp. of hoist motor = (Load in tons × Lifting speed, ft. per min.)/11. This is equivalent to assuming an overall efficiency of 66%. Hp. of trolley motor or bridge motor = $(WS/132)\ (d/D)$, if bearings are bronze bushed; or $SW\{30 + (S/20)\}/33{,}000$, if axles run in roller bearings. In these equations, $W$ = total weight moved, tons; $S$ = travel speed, ft. per min.; $d$ = diam. of axle, in.; $D$ = diam. of wheel, in.

## 3. LOADING AND UNLOADING EQUIPMENT

**ORE BRIDGES AND COAL STORAGE BRIDGES** are gantry cranes with a grab bucket to take ore or coal from boats, cars or a dump to storage, and to reclaim it from storage to cars or boats. As used at Great Lakes ports, these often are bridges spanning 300 ft. or more over the storage area, with cantilever extensions over the water at one end and over railroad tracks at the other. In modern bridges (1936) up to 10-ton buckets have all drums for control of bucket mounted, together with operator's cab, on the trolley. Man-trolley plants, fast in operation and of high capacity, are built (see p. 23–81) by manufacturers [41], [50], [77], [90]. For illustrations and descriptions of various types, see *Trans.* A.S.M.E., 1929, IS–51–4. For methods of operation and description of safety devices, see *Trans.* A.S.M.E., 1930, IS–52–4; also *Demag Nachrichten*, vol. 7B, No. 1, Feb., 1933.

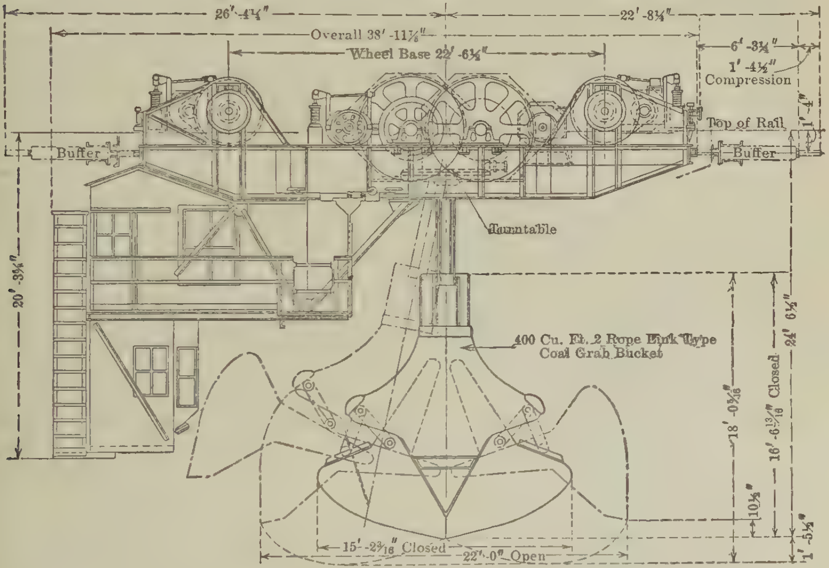

Fig. 15. 10-Ton Man Trolley

In some storage bridges a revolving crane, with a grab bucket on a horizontal boom, runs on the top chords of the bridge. Coal from boats is delivered to a belt conveyor on the bridge and tripped off into storage. In reclaiming from storage, the crane boom swings sideways from the bridge and the grab bucket drops the coal into a hopper delivering to the belt conveyor. Coal can be reclaimed at the rate of 300 tons per hr. (Robins Conveying Belt Co., New York.)

Fig. 15 shows a 10-ton man-trolley. The specifications as given by the makers, Industrial-Brownhoist Corp., are: Maximum moving load, 158,000 lb.; load on ropes, 51,000 lb.; weight of trolley, 107,000 lb.; hoisting speed, 200 ft. per min.; max. height of hoist, 80 ft.; trolley travel speed, 800–1000 ft. per min.; bridge travel speed, 75–100 ft. per min.; bridge moved from trolley cab at any point on the bridge.

**BOAT LOADING.**—At the upper end of the Great Lakes, over 50 million tons of iron ore are loaded into steamers each year. The ore is dug by steam shovel and loaded

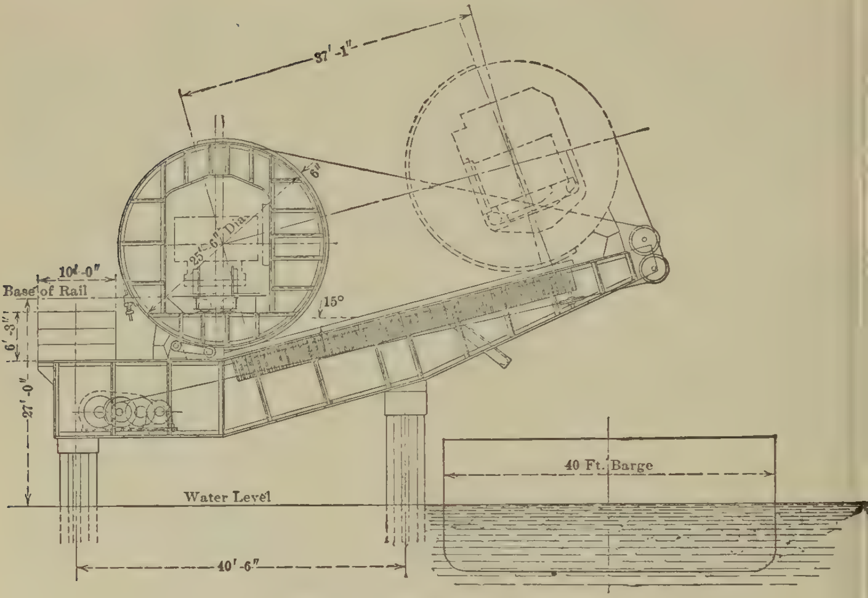

FIG. 16. Link-Belt Car Dumper

into large bottom-dump cars, which at the shipping pier run on high trestles. When the bottom doors open, the ore drops out and runs freely through long chutes into the boat.

On the Atlantic coast, coal is shipped from Norfolk, Baltimore, Philadelphia and other ports the year round. In winter, it sometimes is necessary to thaw the railroad cars in a closed thawing shed before dumping. At some piers the cars run into a rotary dumper, are turned over, and the coal runs into transfer cars. The transfer cars may be lifted to the top deck of the pier to dump their coal into hoppers and ship-loading chutes, or they may travel along the pier and discharge to a conveyor on a boom extending over the boat. In a plant at Baltimore the turn-over motion of the Wellman rotary dump is so controlled that the coal slides out, without much breakage, to an apron conveyor which in turn discharges to the conveyor on the boom. At the end of the boom a vertical chute with a control gate, to ease the fall, delivers coal to the boat. Boats loading coal at Atlantic ports are of all sorts; hatches generally are small, and chutes must be arranged to suit them and to clear ship's rigging. At a coal pier at Pensacola, Fla., a Link-Belt car dumper feeds two bucket elevators, of 300 tons per hr. capacity each. They can discharge at heights variable by 45 ft. to suit a great variety of boats and conditions of loading. Loading chutes have telescopic ends and a horizontal swing of 180°.

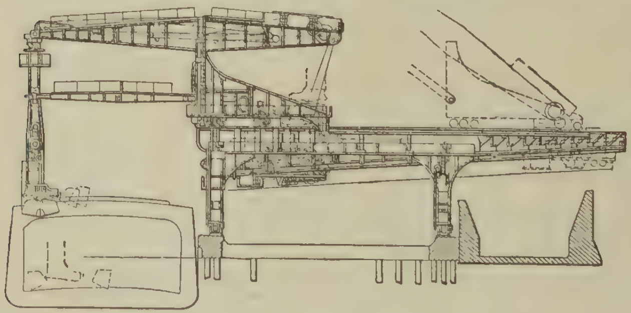

FIG. 17. Hulett Unloader

The large boats bringing ore from the head of the Great Lakes and taking coal back are designed for the purpose. At coal shipping ports, mostly in Ohio, boats are loaded by coal dumpers, generally of the lift type. Fig. 16 shows a Link-Belt rolling dumper which pours the contents of a 40 ft. car into a barge. When car is empty the cradle runs down an inclined track. For history and description of car dumpers, see A. F. Case, *Trans.* A.S.M.E., 1928, MH–50–6. Rotary dumpers and rolling dumpers are made (see p. 23–81) by manufacturers [50] and [90]. The latter also makes lift type car dumpers.

**BOAT UNLOADING.**—Clam-shell buckets are in general use for unloading boats. For intermittent service and small capacities, a mast and gaff with a clam-shell bucket and 2-drum hoist is good and cheap. An inclined boom (gaff) swings around the mast, the bucket being hung from the top end of the gaff. Guide sheaves for holding and closing lines (see p. 23–21) are spread apart at the heel of the gaff, so that the swing of the gaff toward and from a belt hopper can be controlled by putting more tension on one line than on another by means of clutches and brakes at the hoisting machine. Such hoists are used for boats and barges having no rigging to interfere with the swing of the gaff; for rigged boats, a tower with a boom hinged to swing vertically is necessary.

Hoisting towers, with separate hoists to lift the bucket and trolley it on the boom, permit rapid work, as the two motions are simultaneous part of the time. Such towers are made (see p. 23–81) by manufacturers [50], [52], [56] and others. They often work in combination with cable railways or conveying systems to handle coal at storage pockets and power houses on water fronts. To transfer coal or ore from boat to cars or to storage piles, the hinged boom may be a cantilever extension of a bridge tramway.

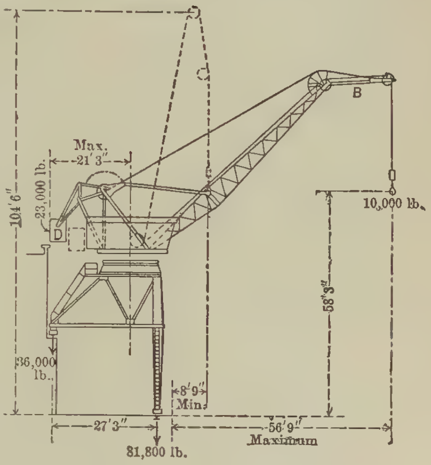

Fig. 18. Level-luffing Type of Crane

The Hulett unloader, Fig. 17 (Wellman Engg. Co.) comprises a gantry frame spanning a number of railroad tracks and carrying a trolley. To the trolley is pivoted a pair of arms carrying a vertical bucket leg. The grab-bucket is fastened to this leg. An operator in the leg controls all motions of bucket, trolley and gantry. A second operator on a traveling scale-larry, hung under the gantry, receives the discharge of the bucket through a hopper holding 3 bucket-loads. After weighing, the larry discharges to railroad cars or to the reserve storage space under the cantilever end of the gantry. Large Hulett buckets spread open to 24 ft., pick up 17 tons of iron ore, and make the cycle of load, traverse and dump in about 50 sec.

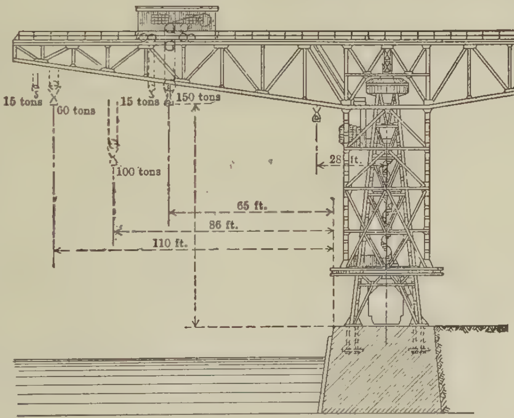

Fig. 19. 150-Ton Hammerhead Crane

**FREIGHT HANDLING TO AND FROM SHIP.**—In the U. S. ships generally are loaded and unloaded by the ship's own winches and rigging. In Europe most of the work is done by wharf cranes, as much of the freight comes and goes in barges without hoisting machinery. To handle freight to and from ships faster and cheaper than by use of the ship's winches, cargo cranes on the wharf must be kept to that one duty and not be burdened with distribution on the wharf. Monorail hoists and tramrail carriers have been used on a few wharves, but electric or gasoline tractors with trains of trailers are more flexible and useful.

Most wharf cranes are traveling gantries with a revolving crane on top of the bridge. Crane booms often are rigged with a " level-luffing " device. Fig. 18 shows one type. Outrigger *B* and counterweight *D* are so mounted that with hoist drum braked, boom can be moved in a vertical plane without raising or lowering the load. The advantages are: Several cranes can work in one hatch without interfering with each other or with the ship's rigging; time is saved; the boom hoist motor may not be so large. See Bernard Dunell, Cargo Cranes, *Trans.* A.S.M.E., 1928, MH–50–5. For methods of weighing the load on the crane according to the tension in the hoisting line, see *Fördertechnik*, Jan. 13, 1933.

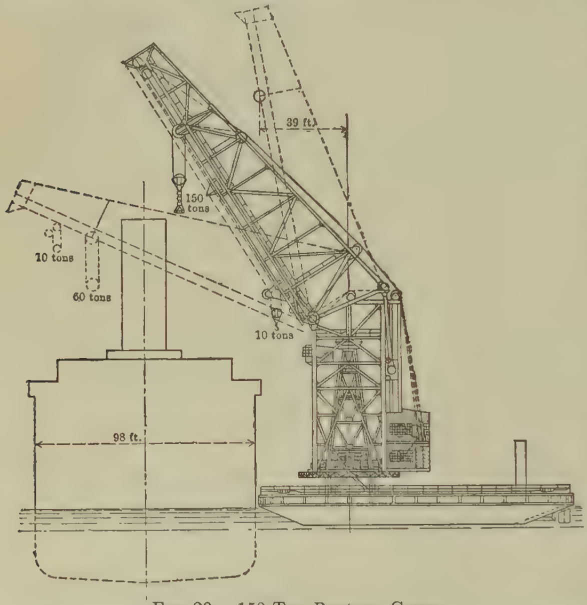

Fig. 20. 150-Ton Pontoon Crane

Cargo cranes generally have a lifting capacity of 10 tons or less, but important European harbors always have some wharves with large cranes to handle heavier loads. Fig. 19 shows a hammer-head crane that will lift 150 tons from a large ship at a distance of 65 ft. from the wharf front, and to 80 or 90 ft. above the wharf. Heavy lifting also is done by pontoon cranes; they often work from the harbor side of the ship while the wharf cranes work on the other side. Fig. 20 shows a 150-ton crane of this kind. It has a Diesel engine power plant for hoists, lighting, and driving the screws which propel the pontoon at a speed of 4 knots. See articles in *Demag Nachrichten*, Feb., 1932, and *Fördertechnik*, Feb. 12, 1932.

# HOISTS

## 1. HAND-OPERATED HOISTS

**HAND POWER HOISTS** (or Chain Blocks) are made in three types: 1. Differential hoists contain two chain wheels above, cast as one piece, and a single wheel below. An endless chain passes over one upper sheave, down around the bottom wheel that carries the load hook, then up over the other wheel. For theory of this device, see p. 8–05. 2. Screw-geared hoists have a worm gear that holds the suspended load by friction of the thread of the worm. 3. Spur-geared hoists have a train of spur-gears with a friction-disc brake of the Weston type to hold the load. See Fig. 1. Type 3, when fitted with ball-bearings, will deliver 85% of the work of the operator to the load-hook. Its mechanical efficiency is about twice that of a screw-geared hoist and nearly three times that of a differential hoist. See Table 1.

Table 2 shows hoisting speeds and pulls on hand-chain for the three types of hoist as stated by one maker. Other makers list the same sizes; their dimensions and ratings are nearly the same. The speed of a chain hoist depends on the pull required on the hand-chain and number of feet of hand-chain overhauled to lift load 1 ft. Speeds given in Table 2 are for short lifts with men accustomed to the work. For easy continuous lifting, use $^2/_3$ of the values given for hoisting speeds. The spur-geared hoist has less internal friction, lifts and lowers load more rapidly than the others. The screw-geared hoist is lighter, takes up less headroom, will work in any position (as for horizontal pulling), and is well suited to work of riggers and repair gangs. The differential hoist is still lighter and serves well for occasional use.

Similar hoists are made (see p. 23–81) by manufacturers [18], [30], [76], [93]. Fig. 1 shows the Cyclone hoist made by Chisholm-Moore. Gearing is compact and entirely enclosed in a grease-filled case. Brake-wheel *A* is keyed to the shaft that carries hand-chain wheel *B*, whose bore is threaded to fit a thread on hub of *A*. The pull of the load-chain on wheel *C* acts through the gears to move *B* to the left, squeezing the leather and steel friction rings against *A*. A pawl engages ratchet teeth on the rim of *A*, prevents the latter from turning and holds load suspended while the friction surfaces are squeezed together. To lift load, *B* is pulled in direction in which ratchet is free, the friction surfaces being engaged. To lower, load *B* is pulled in the opposite direction; it moves on threaded hub of *A* just enough to overcome friction imposed by the load; the pawl engages the ratchet and holds brake wheel when the motion of hand-chain stops. This description applies generally to all screw-type brakes (known also as Weston brakes) used on hand-driven or power-driven hoists.

The Cyclone hoist, in sizes up to 2 tons capacity, also is made with aluminum alloy parts. These hoists are 1/3 lighter than regular hoists, and can be put up and taken down more easily. A safety device throws the hand-chain out of gear if the hoists are subjected to an overload more than the 50% excess over normal rating to which they are tested by the maker. Constants for speed and pull are about the same as those given in Table 2.

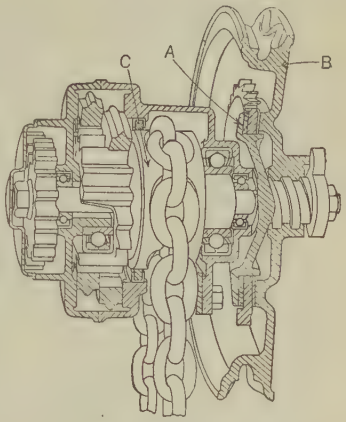

FIG. 1. Spur-geared Hoist with Friction Brake

If it is not convenient for the operator to stand under the hoist, a fixed winch operated

**Table 1.—Comparison of Chain Block Hoists**

| | Differential | Screw-geared | Spur-geared |

* On each of the two hand chains.

by a hand-wheel or by a hand-chain may be used. See Fig. 2. The mechanism is that of a chain hoist enclosed in a box that can be bolted to a wall, building-post or mast of a jib crane. These hoists, up to 2 tons capacity, are listed by several makers.

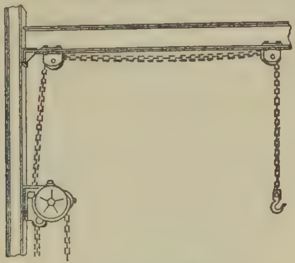

Fig. 2. Spur-geared Hand Winch

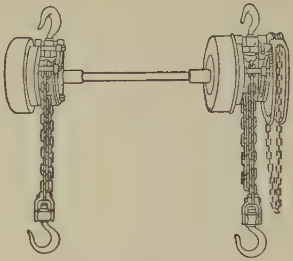

Fig. 3. Twin Hook Chain Block

Hoist makers furnish double hoists, Fig. 3, for lifting lumber, tanks, platforms, truck bodies, etc. They are made in sizes up to 10 tons, and with hoists spaced to suit dimensions of pieces handled. 4- or 8-wheel carriers with double hoists hooked on, or built in. are listed by some builders of tramrail systems.

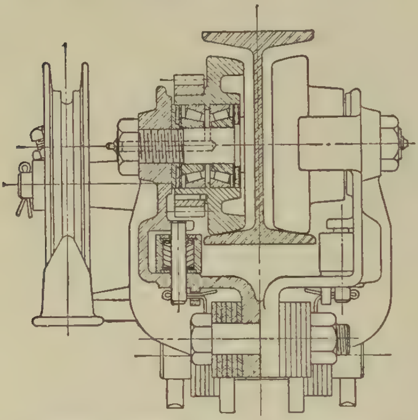

Fig. 4. Geared Trolley for Hand Hoist

The usefulness of a hand hoist can be increased if it is hung from a trolley on an overhead track. If the track forms the bridge of a traveling crane or is attached to a jib-crane, a greater area can be covered. Table 3 gives principal dimensions of trolleys for I-beam tracks. These trolleys are moved by pulling or pushing the suspended load, or are geared and propelled by a hand-chain. The Ace geared trolley (Robbins & Myers) is shown in Fig. 4. It has cast-steel side frames with adjustable spacing for track beams of different widths. The load wheels have no flanges; guiding is done by small rollers which bear against lower flanges of the beam. Similar geared trolleys are furnished by other makers of hoists. Trolleys with 4 or 8 ball-bearing wheels, not geared, are made to take standard makes of chain hoists up to 2 tons capacity, to run on American monorail or Cleveland tramrail tracks. See Fig. 5.

The so-called Army type of chain hoist is a combination of a trolley, either geared or plain, with the hoist mechanism built in. The advantage is that the load-hook can come

* By using spreaders, frames can be widened to suit beams other than standard.

closer to the bottom of the I-beam track. The disadvantage is that the hoist does not work so well if the pull of the load is much off to the side of the track. Fig. 6 shows a hoist of this type, the "Rail Hugger" (Yale & Towne). The hoist is spur-geared with ball bearings; the trolley frame is steel plate; the chilled wheels have roller bearings. Table 4 gives principal dimensions.

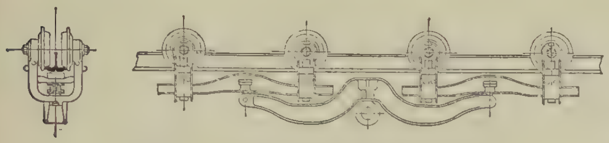

FIG. 5. Trolley to Fit Tramrail Track

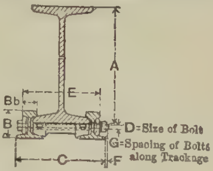

FIG. 7. Double Rail Hoist Track

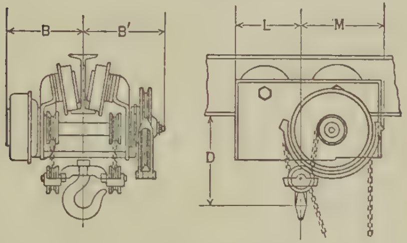

FIG. 6. Army-type Chain Hoist

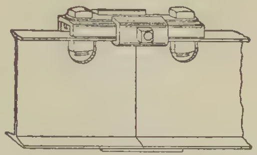

FIG. 8. I-Beam Track Joint

**TRACKS FOR HOISTS.**—Standard I-beams are in general use to carry trolleys of hoists, especially for heavy loads. Common sizes and greatest spans for stated loads are given in Table 3. The beams should be straight; where they join, the bottom flanges should be supported by a plate, otherwise the corners may be bent down by the trolley wheels. It is not usual to splice webs. Supports or hangers are fastened to top flange in various ways to leave room for trolleys. Under frequent passage of heavy loads, lower flanges tend to bend down from peening action of the wheels. This can be prevented by riveting strips to lower flanges to act as a track. The double-rail construction in Fig. 7 serves the same purpose. The I-beam track made by Richards-Wilcox Co., Aurora, Ill., consists of straightened beams; Fig. 8 shows a joint and Fig. 9 an I-beam switch. Pulling the hand chain releases a latch pin, then draws the movable beam over to the next position. A guard plate keeps the trolley from running off the open end of tracks not in register. Similar track work is made by Philadelphia Tramrail Co., Philadelphia, and some builders of hoists. See also Tramrail Systems.

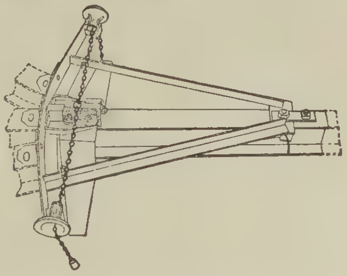

FIG. 9. I–Beam Switch

**Table 4.—Dimensions of Army Type Chain Hoist** (see Fig. 6)
(Yale & Towne Mfg. Co., Philadelphia, Pa.)

| Rated Capacity, tons (2240 lb.) | Standard Size of I-Beam | | Min. Radius of Curvature. | Dimensions, in. | | | | | Standard Lift, ft. | Chain Pull to Lift Full Load, lb. | Chain Overhauled to Lift Load 1 ft., ft. | Speed, ft. per min. |

**PORTABLE HOISTS** of the type shown in Fig. 10 for loads up to 3 tons are made (see p. 23–81) by manufacturers [25], [41], [48], and some hoist builders. They serve where it is not convenient to hang up a chain hoist. Lifting is by a winch built in the frame, or a chain hoist hung from top of the column.

**SPUR-GEAR HOISTS** in capacities up to 1 ton, operated by hand rope or hand wheel, and fitted with automatic stops and safety devices are made by Sedgwick Machine Co., New York, and others. They are fitted with platforms or containers for hoisting or lowering from floor to floor or from sidewalk to basement. Hoists especially designed to lift or lower from basement to sidewalk are also made by manufacturers [25], [32], [48] (see p. 23–81), and others. These machines are also made with electric motor drive.

Small hand-operated counterbalanced hoists for carrying parcels, tools and books rapidly from floor to floor are made by manufacturers [46], [83] (see p. 23–81), and builders of elevators. In some cases, installation of these machines is subject to State Elevator Codes and local regulations in regard to safety and fire.

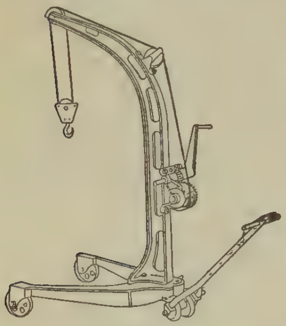

Fig. 10. Portable Hoist

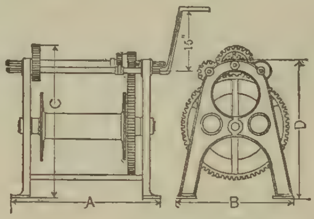

Fig. 11. Portable Hand Winch

**CRABS OR HAND-WINCHES** are made as self-contained units for use with derricks, with block and tackle for riggers, or for lifting through heights beyond the range of chain-blocks. In the portable form, Fig. 11, they consist of two frames carrying a drum with, usually, two sets of gears on shafts with squared ends for the cranks. Sometimes drum-shafts also are squared, to allow slack rope to be taken up quickly by using cranks directly on the drum. One pinion is made to shift in and out of gear, so that cranks can be used on either pinion shaft for different hoist speeds. The load is held and controlled for lowering either by a ratchet and pawl, by a strap-brake or by a friction disc brake of the Weston type. The friction brake will prevent the cranks from accidentally flying back and injuring workmen, as often happens with crabs equipped only with ratchet and pawl. The principle of the Weston brake is shown in Fig. 1. Table 5 gives sizes and dimensions of the style of winch shown in Fig. 11. Fig. 12 shows the same mechanism fitted to flat frames for use on masts of jib cranes and derricks. Simple worm-geared winches of a capacity of 1 ton or less are made in the form shown in Fig. 13 by nearly all makers of conveying machinery.

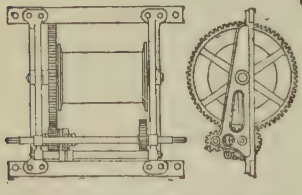

Fig. 12. Hand Winch for Jib-crane or Derrick

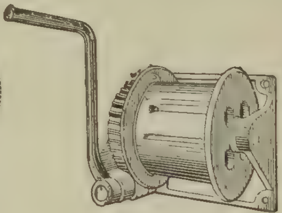

Fig. 13. Worm-geared Winch

**Table 5.—Dimensions of Hand-power Crabs or Winches**

(Industrial-Brownhoist Corp., Bay City, Mich.)

| Pull on Single Line, tons | Barrel Diameter × Length, in. | Dimensions, in. (See Fig. 11) | | | | Weight, lb. |
|---|---|---|---|---|---|---|
| | | *A* | *B* | *C* | *D* | |
| 1/2 | 4 1/2 × 12 | 23 | 22 | 31 | 30 | 230 |
| 1 | 5 × 16 | 30 | 24 | 35 | 32 | 370 |
| 1 1/2 | 6 × 20 | 35 | 27 | 36 | 33 | 520 |
| 2 | 7 × 24 | 41 | 30 | 41 | 35 | 810 |

Throw of cranks 15 in. Larger drums than those listed can be made.

## 2. ELECTRIC HOISTS

**ELECTRIC HOISTS** generally use ball and roller bearings, alloy steels, and heat-treated parts. Pressed steel has been substituted for castings in some designs. Welding has replaced bolting in many cases. Motors usually are enclosed, ball-bearing, and specially designed for hoist work; high-torque squirrel-cage induction motors are more general than direct-current motors. The latter are useful for close control of load movement. Both rope and push-button control are used. Push-buttons give quicker, safer and more convenient control. Electric hoists range in size from $^1/_8$ to 6 tons, with a wide range of hoist speeds. They are made in floor-operated and cab-operated types. For single-speed hoisting, push-button control is the most convenient; one hand is free to steady or guide the load, operation is faster, and the load can be placed more accurately. Cab-controlled hoists are used to transport loads over a considerable distance, where the operator must observe the load from above, or where rapid transfer is necessary.

Worm-driven electric hoists hold the load by friction on the worm thread. Spur-geared hoists use a screw brake (Weston) to hold the load. See Fig. 1. All have a limit switch, to prevent over-travel of hoist hook at top of the lift, and a motor brake to stop the rotor if current fails, and to prevent drifting when controller is in "off" position.

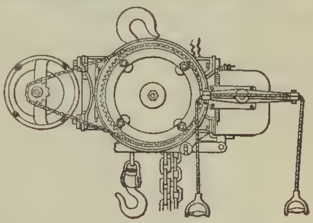

FIG. 14. Electric Chain Hoist

Electric chain hoists are made by manufacturers [18], [95] (see p. 23–81). In Fig. 14 (Yale & Towne) a chain drive from the motor operates gearing like that in a chain hoist. The load is lifted by a chain driven by a pocket-wheel; slack chain is paid out as load ascends. For high lift and for pulling at loads not directly underneath, a chain hoist often is preferable to a rope hoist. Chain hoists are made in sizes of $^1/_8$ to 2 tons.

**SPUR-GEARED HOISTS.**—Fig. 15 shows a hoist built in sizes up to 2 tons (Euclid-Armington). The size of main frame determines distance from overhead track to upper position of hook. It is of steel plate with welded joints, and holds drum, drum shaft and motor brake. Motor and controller are bolted to one side, and an oil tight case with spur gears and brake to the other. All shafts have roller bearings and all load-carrying parts are steel. Table 6 gives dimensions of trolley hoists with drum at right angles to run of track, enabling the hoist to work close to end of the track. With drum axis parallel to track, the hoist can pass through narrow doorways. Similar hoists are made by manufacturers [2], [28], [39], [54], [61], [80], [81], [94] (see p. 23–81). The "Bantam" hoist (Robbins & Myers, Inc.) lists 500 lb. at 30 ft. per min. It is 14 × 21 × 27 in., and weighs 110 lb. without trolley, 145 lb. with trolley. The frame is aluminum alloy with shelf-mounted motor and the usual safety devices.

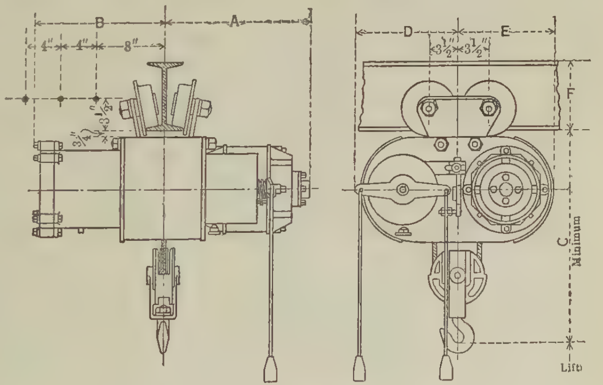

FIG. 15. 2-Ton Spur-geared Hoist

**WORM GEAR HOISTS** are made in sizes up to 6 tons by manufacturers [26], [70], [81]. (See p. 23–81). In this type a hardened steel worm works in a bronze worm wheel.

**Table 6.—Dimensions of Spur-geared Trolley Hoists**
(Euclid-Armington Corp., Euclid, O.)

| Capacity, tons | Standard Lift, ft. | Cable Size, in. | Hoist Speed, ft. per min. | Hp. of Motor | Dimensions, in. (See Fig. 15) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | *A* | *B* | *C* | *D* | *E* | *F* |
| 1/2 | 20 | 1/4 | 30 | 1 1/2 | 18 | 14 | 16 1/2 | 11 1/2 | 10 | 5 |
| 1 | 16 | 5/16 | 30 | 2 1/2 | 18 | 14 | 16 1/2 | 11 1/2 | 10 | 5 |
| 2 | 17 | 3/8 | 25 | 2 1/2 | 20 | 15 1/2 | 18 | 14 | 11 | 6 |

The thread angle is low enough to make the gears self-locking, thus avoiding a mechanical brake. Some hoists have, beside the worm gears, a pair of spur gears to get greater speed reduction between motor and hoist drum. For foundry work, the worm gear hoist can be fitted with special control. A non-spring-return controller used with an over-sized motor gives a speed range from $^1/_{10}$ to full speed, which is useful in handling flasks and molds. A jointed control rod worked by one hand permits operator to use the other hand to guide the load. Fig. 16 shows a 1 $^1/_2$-ton worm-geared hoist made by Electro-Lift, Inc. Overall length is 26 $^1/_4$ in.; distance from bottom of rail to highest position of hook, 14 in. Corresponding dimensions in the 6 $^1/_2$-ton size are 37 and 23 in. respectively.

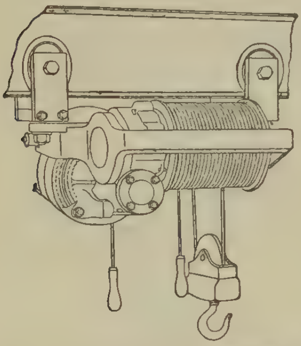

Fig. 16. 1 $^1/_2$-Ton Worm-geared Hoist

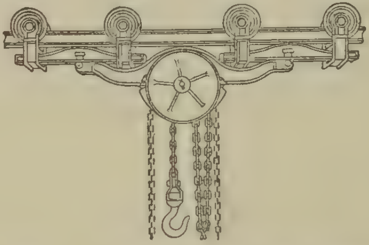

Fig. 17. Tramrail Chain Hoist Carrier

**HOIST CARRIERS.**—Hoists with top hook or clevis may be used as fixed hoists or attached to a commercial trolley. More head-room is required than when trolley and hoist are combined, and wiring is less neat. Most electric hoists can be made with top connections to fasten to an 8-wheel push-type trolley, which are strong, light and can pass curves of small radius. Fig. 17 is typical; overall length is 66 in.; distance bottom of rail to hook, 21 in.

Plain push-type trolleys for I-beam tracks are useful for moderate distances. If load or hook hangs out of reach, or must be spotted accurately, it is better to use a hand-chain geared trolley. If the hoist must travel much, or if the loads are hot, heavy or bulky, the trolley can be motor-driven. (See Fig. 18.) Control cords may be kept away from the hoist by carrying controller on a separate trolley (Fig. 19) when hoist operates through a wide hatchway, from vats or beyond the edge of a platform.

Electric hoists up to 2 tons capacity especially for use with Cleveland tramrail are mounted on 4-wheel hand-propelled carriers for 500-lb. hoists, and 8-wheel carriers for 1- or 2-ton hoists. Fig. 20 shows an electrically propelled carrier mounted with an electric hoist coupled to a trailing operator's platform. Maximum overall length, with single motor drive is 12 ft. 3 in.; operator's platform to bottom of rail, 6 ft. 11 in. minimum; hook to bottom of rail, 29 in. Carriers also are made for pendant cord control, and also with enclosed operating cab. Travel speeds are up to 600 ft. per min. and the carrier can climb grades, run through switches and pass short radius curves. Most builders supply cab-operated machines to travel on single I-beam tracks. For heavy loads and high speeds, the double T-rail track, shown in Fig. 7, is preferable to the lower flange of the I-beam.

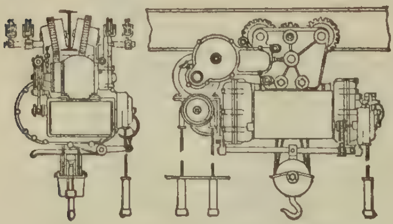

Fig. 18. Motor Driven Trolley Hoist

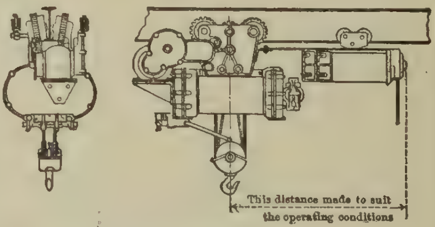

Fig. 19. Motor Driven Trolley Hoist with Separate Controller Trolley

**TELPHER HOISTS.**—In Europe, the track rail for outdoor work usually is a T-rail on a longitudinal supporting beam. The traveling frame, with cab and hoist or grab bucket hangs from the trolleys by hook-shaped hangers which permits some side swing. In England, this is known as the Telpher system. A German monorail carrier of this type, Fig. 21, has no operator but runs under an automatic block control system. Cab control, however, permits higher traveling speed, requires fewer cars, and has less apparatus to maintain.

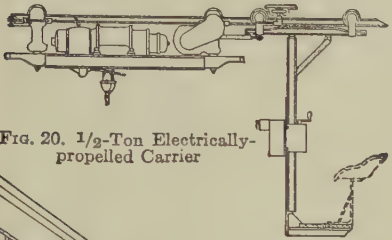

Fig. 20. 1/2-Ton Electrically-propelled Carrier

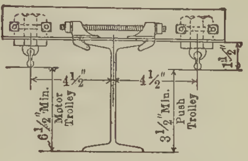

Fig. 22. 8-shaped Conductors and I-beam Track

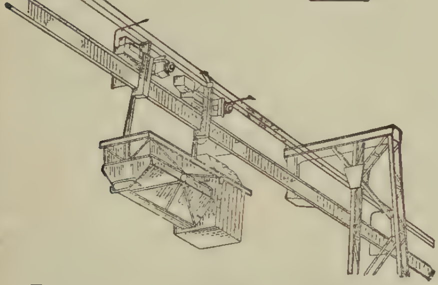

Fig. 21. Automatically Controlled Telpher

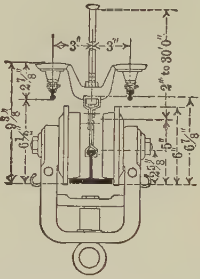

Fig. 23. Tramrail and Electric Conductor Support

**ELECTRIC CONDUCTORS AND COLLECTORS.**—If travel of hoist is short, a flexible cable can be so supported as to allow the necessary movement. If cable drags or interferes, a spring-actuated reel can pay out and take up cable automatically. Such reels are made by Appleton Electric Co., Chicago; J. L. Gleason Co., Boston, and some hoist builders. For long travel, shoe or wheel collectors bear against conductors. These may be copper wire, angle iron, flat bar on edge, or an 8-shaped bar. Fig. 22 shows the latter with an I-beam track, and Fig. 23 a special track and conductor support made for Cleveland tramrail. The American monorail (see p. 23–44) uses small channel conductors on ebonite blocks mounted on the hanger bolts.

To use two conductors with 3-phase current, the primary current is brought through a special transformer. One phase of the secondary current is grounded and connected to the track which is separately grounded. The conductor bars transmit the other two phases. The Cleveland Tramrail Co. in one of its bulletins states that this method of transmitting current to tramrail carriers does not improve operating conditions of alternating-current tramrail motors. Such motors are fundamentally unsuited for conditions requiring delicate speed control and should not be used for extremely severe service. This reference to alternating-current motors applies only to tramrail service, where loads are light and lift is short, and not to hoist and crane service in general.

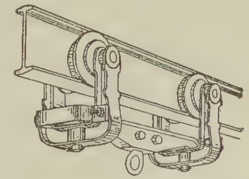

Fig. 24. Special I-Beam Tramrail Track

**TRAMRAIL SYSTEMS.**—The advantages of tramrail systems are: 1. Little machinery required, cost and maintenance low. 2. No floor space required. 3. Switches permit many tracks to be served by few carriers. 4. Overhead tracks for storage of suspended loads avoid the use of floor space. 5. Standard carriers are available for all kinds of bulk and package material.

Louden Machinery Co., Fairfield, Iowa, makes a standard track of I-section, with wide flanges to carry trolley wheels, and for heavier loads a track similar to a 6-in. I-beam with strengthened flanges, one flange wide the other narrow. They are 6 to 16 ft. long, carried by hangers spaced to suit the load. Trolley wheels are drop-forged, ball-bearing, to carry loads up to 5000 lb. See Fig. 24. Trolleys can be driven by motor or operated by hand.

Richards-Wilcox Co. makes an I-beam track (Figs. 8 and 22) for heavy work, and a pressed sheet steel track (Fig. 25) for lighter work, in 10 or 12 ft. lengths of No. 10, 13 or 14 gage steel. Trolley wheels for the size shown are 3 in. diam., ball or roller bearing and are assembled in groups of 4 to 16 with equalizer bars to carry loads up to 3000 lb. The track is made with switches, cross-overs, turntables, drop sections, hangers and brackets to suit different conditions.

Fig. 26 shows American Monorail track, made by American Monorail Co., Cleveland, Ohio, in lengths up to 16 ft., and clamped to drop-forged suspenders. The track is made with staggered joints. It assembles 2 in. wide, 2 1/2 in. deep and will carry loads up to 4000 lb., depending on spacing of hangers and number of trolley wheels. For spans in the open, or where hanger bolts cannot be used, the halves of the rail are welded to the web of a T-beam. Trolley wheels are drop-forged, 4 in. diam., ball bearing, and are assembled in groups of 4 or 8 in carriers with drop-forged wheel yokes, equalizers and load bars.

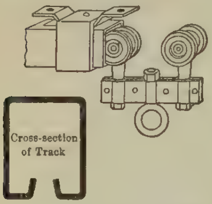

Fig. 25. Pressed Steel Tramrail Track

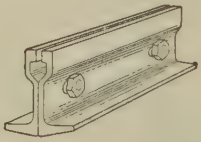

Fig. 26. American Monorail Track

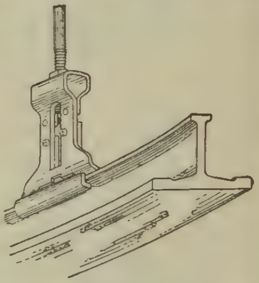

Fig. 27. Cleveland Tramrail Track Support

Fig. 27 shows Cleveland track. It is about 3 × 3 in., 7 lb. per ft. Hanger rods, spaced 3 to 10 ft., support the rail, a clamp on the lower end gripping the rail. A ball-and-socket joint at the upper end permits some free movement, allowing track to adjust itself to load, giving trolley wheels a fair bearing on tread of the rail. On curves, where the load tends to swing outward the rail is free to tilt slightly and wheels on the inside of the curve are not overloaded. Trolley wheels are 3, 4 or 5 in. diam., ball-bearing. Curves, switches, turntables, transfers and fire-door arrangements have been standardized. This sytem uses hand- or motor-propelled carriers, with or without hoists, to carry loads of 500 to 4000 lb. Carriers are made for suspended tiering machines and furnace chargers. Foundry ladles for one-man operation have hoist control buttons on the tilting handle of the ladle. Power-propelled carriers with suspension frames for ladles have controllers for tilt, travel and hoist in the operator's cab or platform. This system also provides automatic dispatch with distance control and special devices for high-speed or continuous travel. See Figs. 28 and 29. With any tramrail system it is possible to arrange track turn-outs to register with various positions of transfer bridges or overhead cranes, enabling carriers to cover a large area.

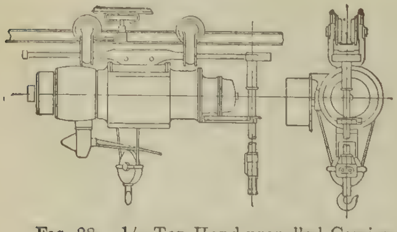

Fig. 28. 1/2-Ton Hand-propelled Carrier

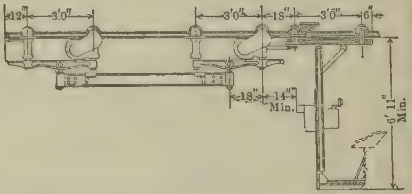

Fig. 29. 2-Ton Electrically-propelled Carrier

## 3. POWER-OPERATED HOISTS

**POWER-OPERATED HOISTS.**—Steam, gasoline and electric hoists for mine, quarries, building erection, logging and grab bucket work are made by manufacturers [3], [21], [29], [49], [56], [96] (see p. 23–81) and others. Single-drum hoists are used for cargo hoisting and building construction, double-drum hoists for general hoisting, and grab bucket work with straight booms. To operate grab buckets on derricks, three drums generally are used, for the holding line, closing line and for luffing the boom, respectively. For operation of grab buckets, see p. 23–20. Swing boom derricks require an extra pair of drums to swing the boom. See p. 23–24. On small rigs, the bucket-holding line can be wound on a drum, separate from the main hoist, operated by a counterweight rope on the same drum and controlled by a brake. With one of these, a hoist with a single drum for the closing line will work a grab bucket (George Haiss Mfg. Co.).

Small winches, winding drums, car pullers and drag scrapers, made to operate by compressed air, are furnished in sizes from 750 to 2000 lb. by manufacturers [42], [86]. (See p. 23–81.) In the Sullivan Turbinair portable hoist, Fig. 30, the air motor is in the hollow of the drum. A 3-Hp. hoist will wind 350 ft. of $^5/_{16}$-in. rope and exert a pull of 1000 lb. at 130 ft. per min. It weighs 175 lb., and is 20 × 15 × 12 in. overall. The handles control clutch and brake. These machines are made with single or double drums or winch heads. They can be bolted to wood or steel plate bases, or clamped to pipe posts or to the masts of derricks. Air-driven hoists mounted on trailer trucks with gasoline engine, compressors and air tanks also are available.

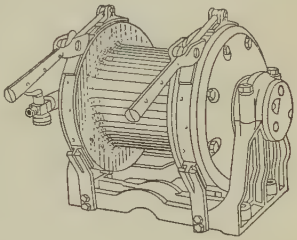

Fig. 30. Single Drum Turbinair Portable Hoist

Many makers of electric hoists supply winches or pulling machines for bolting to floor or ceiling, or mounted on a truck or skids to form a portable winch. American Engg. Co., Philadelphia, makes single-drum pullers of this type in 3 sizes. The smallest is 21 × 23 in., 15 in. high, has a 2-Hp. motor, will wind 250 ft. of $^3/_8$-in. rope, and exert a pull of 1000 lb.

**CAR PULLERS OR SPOTTERS** for moving or spotting freight cars are made by various manufacturers. The Caldwell car spotter (Link-Belt Co.) is a compact machine of the vertical capstan type, with gearing enclosed and running in oil. Two sizes, 5000 lb. and 10,000 lb. pull, are made. The operator throws a few wraps of rope around the capstan and maintains a hand pull on the slack rope as it pays off. See Fig. 31.

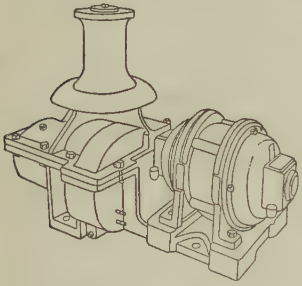

Fig. 31. Car Spotter

**AIR HOISTS FOR SHOP USE.**—Direct lift hoists, Fig. 32, are made by manufacturers [23], [37], [61]. (See p. 23–81.) Cylinders, in diameters up to 19 in. and lengths to suit the work, have lifting capacities up to 10 tons at 80 lb. per sq. in. air pressure. They are made single-acting for simple rapid lifting, or as balanced-pressure cylinders, in which air acts at full pressure on one side of the piston but is varied on the other by a hand-operated valve. The piston moves under a difference of pressure, and speed and travel are accurately controlled. Air cylinders can be hung from trolleys if the travel is not too great.

Advantages claimed for direct acting air hoists are: 1. They will work under conditions of dust, moisture, fumes, etc., injurious to other hoists. 2. Few parts to get out of order; repairs can be made by any mechanic. 3. Accuracy of control. 4. Low first and operating cost, including maintenance and depreciation.

**GEARED HOISTS** operated by compressed air are made by manufacturers [42], [97]. (See p. 23–81.) A balanced 2-, 3-, or 4-cylinder engine drives a wire rope drum or chain pocket-wheel, through gears enclosed in a tight lubricant-filled case. Sizes range from 500 lb. to 10 tons capacity. They weigh 2 or 3 times as much as hand chain hoists but are lighter than the ordinary electric hoists, especially in smaller sizes. They are useful in shops and foundries where compressed air is available and where the hoist can be hung from a fixed point or a trolley with travel not too long for the air hose. They are not easily affected by heat and dust in foundries, and since the valve control is accurate and delicate, patterns, cores and flasks can be handled with certainty and safety. Similar hoists with engines of the square piston type are made by Dake Engine Co., Grand Haven, Mich.

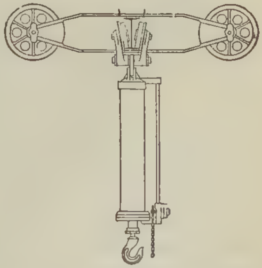

Fig. 32. Direct-lift Air Hoist

# GENERAL CONVEYING AND ELEVATING

## 1. COAL HANDLING IN BOILER HOUSES

**BASIC FACTS FOR BOILER HOUSE DESIGN.**—(Abstracted from Catalog 50 of R. H. Beaumont & Co., Philadelphia.) Assuming that boilers are run at 150% of rated capacity, and a load factor of 66 percent and that the coal consumption is 3.5 lb. of coal per boiler Hp.-hr., then 1000 boiler Hp. requires $1000 \times {}^3/_2 \times {}^2/_3 \times 3\,{}^1/_2 = 3500$ lb. per hr. = $1\,{}^3/_4$ tons per hr. Coal handling machinery should be able to handle a one-day supply in ${}^1/_2$ of an 8-hr. shift. Its capacity therefore should be $10\,{}^1/_2$ tons per hr. per 1000 boiler Hp. The supply bin should hold at least enough for a one-day, or better, a two-day run. The coal larry should be able to handle the daily supply in not more than 8 hr. Stoker hoppers should contain a 3-hr. supply if possible. Good quality bituminous coal produces 10% ash; poor quality, 20%; anthracite culm, 60%. If ashes are handled only on day shift, and in 5 or 6 hr., ash hoppers under the stokers should hold a 16- to 20-hr. run of ashes. If ashes are handled on two or three shifts, ash hoppers can be smaller, height and cost of building less, and hourly capacity of ash handling machinery also can be smaller. Ashes best can be discharged from a storage bin to railroad cars or trucks by daylight The bin should hold a one-day run. If ashes are to be moved in railroad cars the bin should hold a carload plus a margin for uncertainty of car supply.

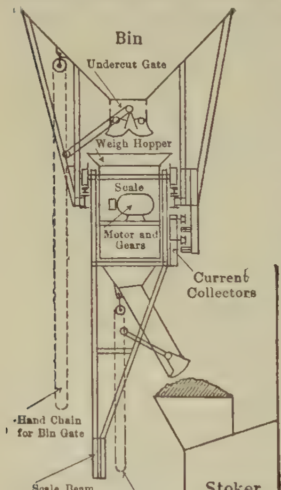

Fig. 1. Floor-operated Weigh Larry

**COAL HANDLING IN BOILER HOUSES.**—Whether it will pay to install coal handling machinery in an old boiler house depends on amount of coal used, probable remaining life of old boiler house, how coal is received, and the ease or difficulty of adapting machinery to the place. All new boiler houses using coal should be designed for coal handling machinery and storage. Even in boiler houses using as little as 5 or 10 tons per day, a simple coal elevator or conveyor usually will pay its way.

Nearly all modern boiler houses use mechanical stokers or burn pulverized fuel, and must have machinery for crushing the coal, elevating and storing it, and feeding it to stokers or pulverizers. Both systems require crushed coal. In small plants it usually is possible to store enough coal in a covered overhead bin to supply boilers regularly and have enough reserve for ordinary contingencies of interrupted coal supply or accident to machinery. In large and important plants reserve storage is necessary to avoid risk of boiler shut-down and also to permit coal to be bought at favorable times and prices. The reserve storage is usually a pile in the open, formed by dumping from an elevated trestle, or by a crane or conveying machinery, or spreading by means of a drag scraper. Fig. 4, p. 23–16, shows a boiler house with an external storage bin and a reserve storage, spread and reclaimed by a drag scraper.

**DESIGN OF BIN.**—In the structural design of a new boiler house, the size and location of storage bin must be determined first. It should hold at least enough coal to carry the plant during interruption to car service or repairs to coal handling machinery. If the bin is directly in front of the boilers, the bottom should be high enough from the floor to avoid interference when boiler tubes are cleaned or replaced. Bins should not obstruct the light. Spouts from stokers should be at 45° or more from horizontal. If the bin is in the house and runs its full length, bottom gates placed close together, serving a traveling hopper, permit more stored coal to be drawn off than would flow to spouts placed to match stokers. The traveling hopper generally is a weigh-hopper to check weight of coal delivered to each boiler. If the bin is outside or at one end of the house, its height is fixed by the traveling hopper, but the boiler house structure can be designed without reference to the bin or its weight. The roof can be lower, and size and shape of bin itself can be independent of restrictions imposed by boiler house dimensions. An outside bin generally is short and can be filled by a simple elevator or skip hoist, whereas a long bin in a boiler house requires more machinery. The structure supporting an outside bin also can house coal handling machinery, and also may carry ash handling machinery and ash storage. In small plants, one skip hoist or one pivoted bucket carrier may handle both coal and ashes.

Fig. 1 shows a weigh-larry operated from the floor; others are cab-operated. Some control opening and closing of bin gates to avoid spilling coal on the floor. The gate will open only when larry is under it and must close before larry can move. Larries are made from 1/2 ton to 10 tons capacity, or more, by most makers of coal handling machinery. In plants with not more than 3 or 4 boilers it is possible to use a separate stationary weigh-hopper at each stoker spout. The investment in scale mechanism, however, is greater and probably there is no saving in labor.

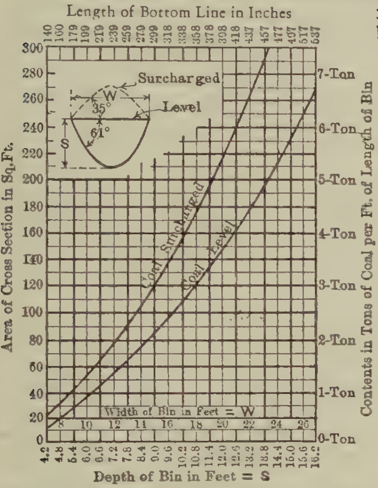

FIG. 2. Capacity of Coal Storage Bins

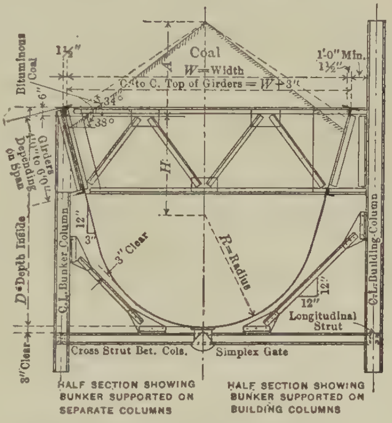

FIG. 3. Beaumont Suspended Coal Bunker

**Shape of Coal Storage Bin.**—In some boiler houses a round tank with a conical bottom, holding 5 to 20 tons, opposite each stoker or pair of stokers is sufficient. When greatest possible storage in boiler house is necessary, the bin may be continuous for the entire length of boiler or of house. Continuous bins can be built most economically as part of the boiler house structure and hung either from roof trusses or supported on building columns. The slope of the bottom always should assist movement of coal toward the spout, and also lessen the danger of fire in deep bins. The best bins, in which weight of structure is low per ton of contents, are the round-bottom suspension type. The steel sides act in direct tension to carry the weight as well as to resist thrust of the coal. Fig. 2 (Link-Belt Co.) shows relations between dimensions of such bins and their capacities in tons of coal, based on a bin depth of 0.6 bin width and with level fillings or a surcharge at a slope of 35°. Fig. 3 (Beaumont) and Table 1 give dimensions of bins where depth is about 0.8 × width, and capacities based on a surcharge at an angle of 38°. The last

column refers to the fact that full length of bin cannot be surcharged unless the ends are built higher than the bin body.

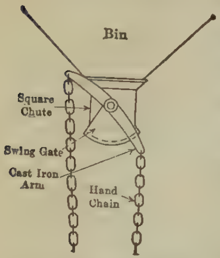

Fig. 4. Swinging Undercut Bin Gate

It is unnecessary to line round-bottom suspension bins with reinforced concrete to prevent corrosion. Coal does not rub the plates except at gate openings where there is some steel reinforcement. Bins for washed anthracite or high-sulphur coal are coated inside with a plastic bituminous cement to resist corrosion.

**Bin gates** should be of the undercut type, Fig. 1 or Fig. 4. Slide gates may stick and are hard to work. Spouts should be at least 12 in. diam., or better, 12 × 12 or 16 in., as wet coal is less apt to stick in large spouts. Openings from bins to stoker spouts should always be controlled by a gate to permit removal of spout for repairs or cleaning or replacement of boiler tubes.

**PULVERIZED COAL IN BOILER HOUSES.**—Two principal systems are: 1. The bin system. 2. The unit pulverizer system.

**Bin System.**—Coal from storage is dried, pulverized, conveyed by a pneumatic system (see p. 23–67) if distance is long, or by screw conveyor if distance is short, to a bin at the boiler. An adjustable feeder under the bin delivers pulverized coal to a blast pipe, thence to the burners. Advantages of this system are: 1. Feed to furnaces can be varied instantly. 2. Coal can be pulverized in off-peak period. 3. Machinery is kept away from the boiler (see H. Kreisinger, *Trans.* A.S.M.E., 1930, FSP–52–36).

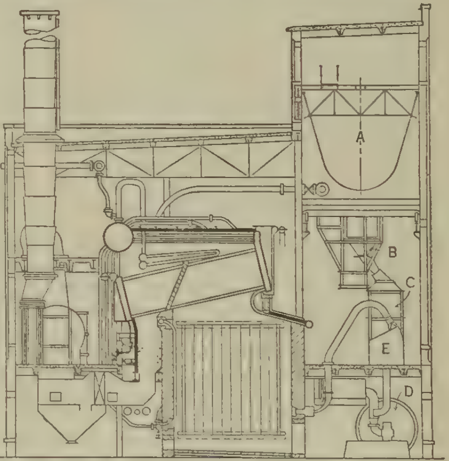

Fig. 5. Kennedy-Van Saun System of Pulverized Fuel

**The Unit Pulverizer System** stores no pulverized coal. The pulverized coal is burned as it is made; it is unnecessary in most cases to dry the coal. Fig. 5 shows the Kennedy-Van Saun system. Crushed coal is stored in bin *A*, drawn off and weighed by larry *B*, stored in small hopper *C*, delivered by an adjustable feeder to tube mill *D*, then as fine dust through blower *E* to the furnace. Pulverizing, conveying and blowing equipment is made by manufacturers [31], [35], [43], [45], [75] (see p. 23–81).

**HANDLING COAL FROM CARS.**—The problem in most boiler houses is to take run-of-mine bituminous coal from railroad cars, crush it and elevate it to bins. In small plants, small anthracite is burned, or lumps of soft coal are broken on a grating over the track hopper or on the boiler room floor by the fireman. The apparatus comprises a track hopper delivering to a simple elevator, Fig. 6, or to an inclined conveyor, Fig. 7. A pile so formed will serve one or two boilers by direct spread on the floor, but for more boilers, a distributing conveyor, Fig. 8, is advisable. To distribute coal in an overhead bin, a scraper conveyor, a belt conveyor or a pivoted bucket carrier can be used in combination with any of the above methods. If the return run of a pivoted bucket carrier can be placed below the boiler room level, it also may be used to remove ashes to a bin.

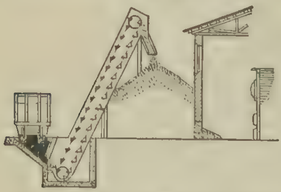

Fig. 6. Track Hopper and Elevator

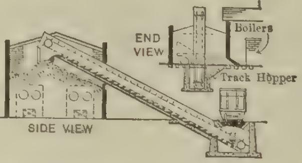

Fig. 7. Track Hopper and Conveyor

If coal is to be crushed, flow from track hopper must be controlled by a feeder. For small anthracite, it generally is sufficient to use a slide gate. For soft coal, smaller than run-of-mine, where flow is direct from track hopper to elevator or conveyor, and where the rate of handling is slow, an undercut gate, hand controlled, can be used. To avoid risk of flooding conveying system, and to prevent breakdowns, a feeder generally is advisable.

**TRACK HOPPERS** can be made as part of a concrete foundation, especially in small sizes and where no feeder is used. That shown in Fig. 6 has a hand-operated undercut gate. If a feeder is used, it is most convenient to attach the parts to a steel hopper. If proper access is provided to back and both sides of a feeder, concrete construction becomes costly. Steel track hoppers usually are of $^1/_4$-in. plate with angle stiffeners. At track level they should be at least 10 ft. wide to give room for lump between track girders and hopper sides. Hoppers above ground level or on trestles should be 14 ft. wide to catch flow from car doors and to prevent spill. In general, hoppers 14 ft. wide are advisable for rapid unloading of bottom-dump cars. Length of hopper along tracks should be at least 12 ft., but for quick work with the largest cars 24 ft. is better, as it will take half the discharge of a car at one setting. Link-Belt Co. has made hoppers 40 to 44 ft. long to empty a car at one setting. Such hoppers have a double-acting plate-feeder working parallel to the track. Track hoppers for skip hoists usually have automatic gates to fill the skip to capacity without spilling. See p. 23–50.

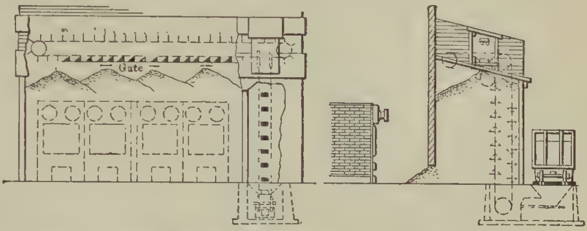

Fig. 8. Track Hopper, Elevator and Distributing Conveyor

Track girders consist of double I-beams, plate-and-angle girders, or Bethlehem wide-flange beams. They must be designed for dead loads, live loads and impact to meet railroad specifications, and generally are subject to the approval of railroad engineers. See Stephens-Adamson Mfg. Co., catalog No. 30 for design based on such specifications.

The time required to spot a car, open doors, get coal out, close doors and move car away varies with the size of car and the weather. Under favorable conditions, the total time for a 50-ton car may be 30 min.; for a 100-ton car, 45 min.; that is, rate of delivery to a one-track hopper varies from about 2 tons a minute in good weather, to, say, 1 ton in bad freezing weather. A one-track hopper will feed a continuous conveying system if average hourly capacity is not over 100 tons. The size of hopper is not important if its area at track level allows the car to be unloaded without difficulty. If a continuous system must deliver more than 2 or 3 tons per min., it may be necessary to dump on two tracks or to use a rotary car dumper. If track hopper delivers to a car or skip, volume of the hopper must be such as will keep skip supplied during those intervals when no coal enters the hopper. A proper size is: Hopper capacity, tons, = 0.80 × rated capacity of skip hoist, tons per hr. Fig. 9 shows a rotary car dumper feeding a skip hoist.

Fig. 9. Rotary Car Dumper Feeding Skip Hoist

**COAL CRUSHERS.**—The kind, size and speed of crusher depends on the kind of coal, whether hard or soft, size of largest pieces, size to which it is to be crushed and quantity per hour. For dimensions, capacity and power required by single- and double-roll crushers, see catalogs of makers of conveying machinery. For crushing finer than 1 in. in large capacities, hammer mills or ring roll mills often are used. To prepare coal in large quantities for subsequent pulverization, the Bradford breaker often is used instead of roll crushers. As made by the Pennsylvania Crusher Co., Philadelphia, and others, it is a steel cylinder 6 to 12 ft. diam., 8 to 20 ft. or more long, with a shell of perforated steel plate. Coal fed in at one end of the cylinder is lifted up and tumbled until it is small enough to pass the perforations. The hard slaty refuse and stray iron are rejected at the other end of the cylinder. The machine acts both as a crusher and as a separator and protects pulverizing and conveying machinery from damage.

**SKIP HOISTS** comprise a single-drum winding machine, a wire rope, a skip or bucket which takes its load below, and dumps it above, together with the necessary lead sheaves, skip filling device and electrical control apparatus for the winding machine. Skip hoists are simple in construction and relatively cheap to maintain and operate. Carrying capacities can be made to suit the smallest or largest boiler houses. The path of the skip can be vertical, inclined or a combination of both. Carrying capacities depend on size of skip, speed of travel, method of loading, whether or not the skip is counterbalanced, and whether operation is full or semi-automatic. Makers' catalogs give tables of expected capacity under various conditions. Skip hoists have been well standardized by manufacturers [11], [50], [98], (see p. 23–81), and other makers of conveying and hoisting machinery. Their catalogs give detailed information about track hoppers, loaders, skips, steel structures, winding machines and electrical control apparatus. Fig. 10 shows a skip hoist where an apron feeder was used to reduce the depth of pit under the track hopper. This arrangement is not recommended. It is simpler and better to feed directly from the track hopper through a chute.

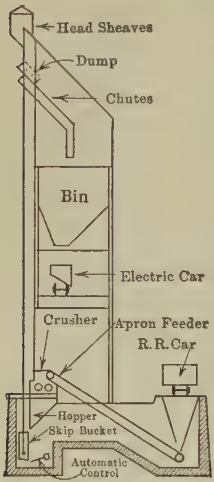

Fig. 10. Skip Hoist

**Skip Hoist with Traverse Motion.**—A form of skip hoist, first used to load anthracite or coke to silo bins in retail coal yards, is made by manufacturers [33], [50], [99]. (See p. 23–81.) A latched-bottom bucket takes its load of 1 or 2 tons from a track hopper with an automatic feed chute. When hoist is started the bucket rises, comes in contact with a trolley carriage, moves horizontally to a chosen point, then lowers. When bottom of the bucket touches material in the bin, the doors open and contents slide out. The bucket then returns for a new load. Some of these hoists have full-automatic push button control. See F. D. Campbell, *Trans.* A.S.M.E., 1931, MH–53–1; also W. W. Sayers, *Trans.* A.S.M.E., 1931, MH–53–8.

## 2. CARRIERS AND ELEVATORS

**PIVOTED BUCKET CARRIERS** consist of round-bottom buckets, pivoted between two long-pitch roller chains, arranged to dump on a horizontal run by tipping the bucket. They can be run vertically, horizontally, or in an inclined path. Suitably combined with crusher and feeder, they fit many arrangements of railroad track, boiler house and storage bin. Where lift, travel and capacity required are not too great, a pivoted bucket carrier is economical, and convenient to install and operate. If carrier is not used for coal more than an hour or two a day, it may in some cases also be used for ashes. If ashes are in large clinkers some other system will be better.

Most carriers of this type have overlapping buckets which can be fed continuously from a chute. The chains have hardened pins and bushings, self-oiling rollers and other refinements. The difference between different makes is chiefly in the suspension of the buckets, and making them lap properly at corner turns. Sizes of buckets, capacities, clearances, power required are practically the same for all such carriers made in the U. S. See Tables 2 and 3.

The horsepower required at the head-shaft of a pivoted bucket carrier is

$$\text{Hp.} = AL + BR \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [1]$$

where $L$ = total vertical lift, ft., $R$ = total horizontal run, ft.; $A$ and $B$ are factors whose value is given in Table 3. Add 10% for each cast gear drive, and 5% for each drive through belt, chain or cut gears.

Pivoted bucket carriers are quiet in operation, convey and elevate at the same time and thus avoid transfers and deep pits. They require little power. They cannot be fed on a vertical run nor under a turn wheel. The dump must always be on a horizontal run. Catalogs of manufacturers [17], [44], [50], [85], [89], (see p. 23–81), give dimensions of drive groups, corner turns and clearances.

**CENTRIFUGAL DISCHARGE ELEVATORS.**—The simplest form of elevator consists of malleable-iron buckets fastened at intervals to a single chain. It is called a "centrifugal discharge" machine because the contents of the buckets are thrown out at the head-wheel by centrifugal force. A full, clean discharge into the head-chute depends chiefly on the size of the head-wheel, its speed and the bucket spacing. Table 4 gives the result of practical experience with vertical centrifugal discharge coal elevators.

Belts with buckets attached are used for fine, dry or gritty materials, but chain is better for the rough work of elevating coal. Fig. 11 shows Style A malleable-iron buckets, used in coal elevators. The buckets will not discharge clean if set too closely together. For analysis of conditions of pick-up and discharge of centrifugal bucket elevators see Belt Conveyors and Belt Elevators, by F. V. Hetzel. (John Wiley & Sons.)

Table 5 gives the closest possible spacing for the speeds given in Table 4. If spacing does not match pitch of chain, increase it to a multiple of that pitch. If the coal is lumpy, increase the spacing. To determine the size of chain, working strengths alone, as given in makers' catalogs, are not a suitable guide A link should be chosen which bears a proper proportion to the dimensions of the bucket, and which has a bucket attachment large enough for the bucket. K 1 attachments have two bolt holes; K 2 attachments have four bolt holes and are advisable for buckets 8 × 5 in. and larger. The greater the projection of the bucket, the greater should be the pitch of the link to give the bucket a proper support in picking up its load. Table 6 represents good practice.

### Table 7.—Weights and Capacities, Style A, Malleable-iron Buckets

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Size of bucket, in., length × projection | 6×4 | 7×4 1/2 | 8×5 | 10×6 | 12×7 | 14×8 | 16×8 |
| Weight, lb. | 2.2 | 3 | 4 | 6.4 | 9.6 | 13.2 | 21 |
| Coal capacity, lb. (*C* in formulas) | 1.5 | 2.2 | 3 | 5.2 | 8.3 | 13.9 | 18.9 |

Table 7 gives weights and capacities of buckets used in simple coal elevators. The diameter of the foot-wheel of a centrifugal discharge coal elevator should be at least four times the pitch of chain used. If the wheel is too small, buckets will not fill properly. The following formulas are applicable to bucket elevators:

**Notation.**—$C$ = lb. coal per bucket (see Table 7); $D$ = diam. of foot-wheel, in.; Hp. = horsepower to be delivered to the elevators; $L$ = height of lift, ft.; $P$ = pull in chain, lb., due to pick-up of coal at foot of elevator; $S$ = spacing of buckets, in.; $T$ = travel of chain, ft. per min.; $U$ = unbalanced pull in chain due to weight of coal in buckets; $W$ = capacity of elevator, lb. coal per minute; $X$ = theoretical horsepower required.

$$P = 12\,DC/S \qquad [2]$$

$$U = 12\,LC/S \qquad [3]$$

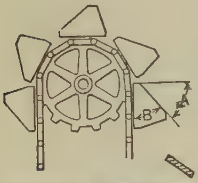

Fig. 12. Continuous Bucket Elevator

Combining [1] and [2],

$$X = 12\,(C/S)(L + D)(T/33{,}000) \qquad [4]$$

Allowing 30% for losses in power transmission,

$$\text{Hp.} = 0.0005(CT/S)(L + D) \qquad [5]$$

$$W = 12\,CT/S \qquad [6]$$

The head-chute of a centrifugal discharge coal elevator should have a slope of at least 35 deg. and its upper end should not be above a line drawn at 45 deg. through the center of the head-wheel.

The lower wheel of a centrifugal discharge coal elevator generally is enclosed in a cast-iron or steel plate box, called a boot, which serves as a support for shaft bearings and also confines material to the path of the buckets. Boots with fixed bearings generally are not used for coal elevators, those with adjustable bearings being convenient. For sizes and dimensions, see makers' catalogs. For diameter of head-shaft, see p. 23–56.

**Advantages and Limitations.**—The centrifugal discharge elevator is cheap and simple, takes up little space, does not require deep or large pits, and can be encased easily. It will give good service when worked for a few hours each day, but for lumpy material, large capacities and long hours of service, it is better to use a heavier machine at slower speed. Such machines comprise continuous bucket elevators, perfect-discharge elevators, and V-bucket elevators.

**CONTINUOUS BUCKET ELEVATORS** consist of single or double chains with an endless series of steel buckets so shaped that in passing over the head-wheel each bucket acts as a deflector or chute for the discharge of the contents of the following bucket. Single strand machines use K 2 attachments fastened to the backs of the buckets, the depth of the bucket being 2, or rarely 3, pitches of the chain. Angles usually are fastened to the bucket ends to guide the vertical runs. Long buckets for large capacities require two chains, fastened to the ends. The chains usually are of steel, with a pitch equal to the depth of the bucket. In this position the chains guide the vertical runs. For inclined runs, they can be fitted with rollers that run up and down on suitable tracks. Buckets for vertical elevators handling crushed coal, Fig. 12, are made with the angle $B$ in the bottom equal to 55 deg., thus giving a chute or discharge angle of 35 deg., which is steep enough for crushed coal. If the coal is all fine or wet, $B$ should be 45 deg.; angle $A$ then is 45 deg., giving a better delivery into the head-chute. When the elevator is inclined 25 or 30 deg. from the vertical, as in Fig. 13, $B$ can be increased to 70 deg. to give more bucket capacity, and for ordinary crushed coal the discharge will be clean. This is one advantage of inclining such an elevator; another is that material can be delivered directly to the buckets by a chute without spill. These buckets will pick up soft material like crushed coal from a boot, but not hard lumpy material like stone. Stone and ores should be handled in inclined elevators, with the feed directly from a chute set 2 or 3 buckets above the foot-wheel, and the foot of the elevator must be free and open to allow spilled material to fall clear of the buckets and be shoveled up. The head-chute never must be above a line drawn at 45 deg. through the center of the head-wheel. Speeds range from 90 to 200 ft. per minute in handling coal.

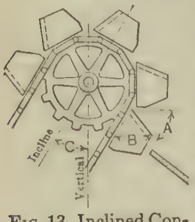

Fig. 13. Inclined Continuous Bucket Elevator

For horsepower required by continuous bucket elevators, use formula [5]; for capacities use formula [6]; for diameter of head-shaft, see p. 23–56.

The continuous-bucket elevator is especially adapted for handling stone, but in elevating crushed coal for boiler houses it has the merit of giving high capacities at speeds much lower than those of centrifugal discharge elevators. For handling run-of-mine or large lump coal the V-bucket elevator is generally better.

**PERFECT-DISCHARGE ELEVATORS** have two strands of chain fastened to the ends of the buckets. The buckets are not continuous and the speed is slow as compared with centrifugal discharge elevators. In order to effect a clean discharge, the chains are deflected backward under the head-wheels by a pair of supplementary wheels in such a way that the contents of each bucket will fall clear of the bucket ahead. Fig. 14 shows the location of the deflector wheels with reference to the head-wheels. Table 8 is based on good practice and gives dimensions for elevators using malleable-iron, Style A buckets and with wheels arranged according to Fig. 14. These elevators often are built with sheet steel buckets for larger capacities of coal, at speeds between 100 and 150 ft. per minute.

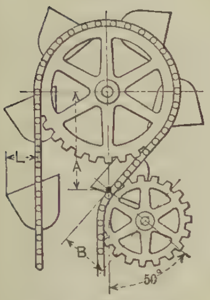

Fig. 14. Perfect-discharge Elevator

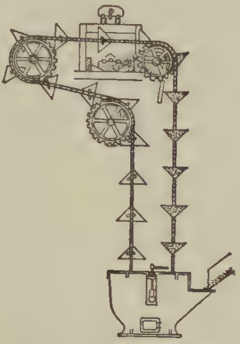

Fig. 15. V-Bucket Carrier

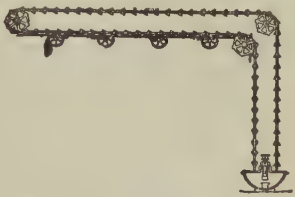

Fig. 16. V-Bucket Carrier with Boot

Measure *A* down from center of head-wheel. Draw line 50 deg. from vertical. Measure *B* from intersection to center of deflector.

For horsepower use formula [5]; for capacities use formula [6]; for diameter of head-shaft, see p. 23–56.

**Advantages of the Perfect-discharge Elevator.**—1. It has two chains, and as usually designed, has a large margin of safety between the working strain and the breaking strength of the chains. 2. The pick-up of material is easy. 3. On account of the slow speed, the chains, buckets, wheels, gears and bearings last longer and require less attention and repair. As an offset, the machine costs more than a single-strand elevator.

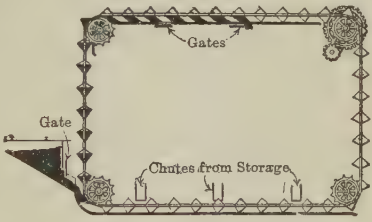

Fig. 17. V-Bucket Carrier in Boiler House

**THE V-BUCKET CARRIER GRAVITY DISCHARGE MACHINE** is used extensively for handling coal, either lump or crushed. It consists of two roller chains fastened to the ends of V-shaped buckets which carry the coal on vertical or inclined runs and push it along a trough on the horizontal run. Gates in the trough permit the coal to be discharged where it is wanted. When arranged as in Fig. 15, or Fig. 16, it will pick up from a boot; with the path shown in Fig. 17, it will pick up at any point on the bottom run as well as at the corner turn. In boiler house work, machines arranged as in Figs. 15 and 16, will take coal from a track-hopper, a feeder or a crusher, elevate it and discharge into a belt or flight-conveyor for distribution in overhead bins. The machine arranged, as in Fig. 17, can form a storage pile near the boiler house, or by discharge into an overhead conveyor, transfer direct from cars to the boiler house. Coal is reclaimed from storage by delivery into the lower run located in a tunnel beneath the pile. It is then elevated and discharged to the overhead conveyor for distribution in the boiler house.

Table 8.—Data for Perfect-discharge Elevators, Style A Buckets

| | | | | | | |
|---|---|---|---|---|---|---|
| Projection of bucket, in. | 5 | 6 | 7 | 8 | 9 | 10 |

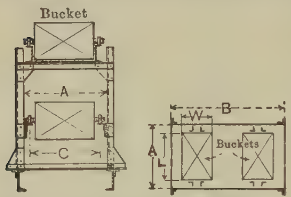
Figs. 18 and 19 show typical cross-sections. Table 9 gives capacities and dimensions for sizes commonly used in boiler houses. Table 10 gives the horsepower required for some of the sizes.

The 12-in. and 16-in. buckets sometimes are carried on malleable-iron roller chains, but steel bar chains generally are used for the larger sizes, and are better for the small sizes also. Take-ups or adjustable bearings always should be placed at a corner where the buckets pass empty, not at a corner around which coal travels. Vertical runs always should be encased to confine the spill and to avoid exposure to rain and snow.

**Advantages of V-bucket Carrier.**—1. Strong and rugged; will carry any coal up to run-of-mine size, at speeds up to 120 ft. per minute. 2. Will receive on any run or from a boot. 3. Handles coal without breaking it. 4. Gives larger capacities than pivoted bucket carriers.

**Disadvantages.**—1. Requires more power on horizontal runs than other types. 2. Not suitable for ashes or hard and gritty material. 3. As compared with other elevators, it cannot discharge over a head-wheel, but always must discharge on a run between two sets of wheels.

**HORIZONTAL DISTRIBUTION BY BELT OR FLIGHT CONVEYOR.**—Inclined conveyors sometimes are used for elevating coal when the boiler house is at a distance from the track. If the house is not too long, the inclined conveyor may be carried over a hump into the horizontal, but if the house is long, or if its axis is not in line with the conveyor from the track, a separate conveyor must be used for distribution in the house. A similar condition exists in boiler houses where the ash disposal is by car or hoist. In such cases, where a pivoted-bucket or a V-bucket carrier cannot well be used for distributing, a simple coal elevator or a hoist is used for lifting the coal.



Figs. 18 and 19. Cross Sections of V-Bucket Carrier

Whether to use a belt conveyor or a flight conveyor depends partly on the structures and operating conditions, and partly on the personal preferences of engineers and owners. Considering only physical conditions, belt conveyors may be regarded as best: 1. Where the bin is long, say, 150 ft. or more. 2. Where the capacity is more than 100 tons an hour. 3. Where noiseless operation is essential.

A flight conveyor may be best: 1. Where there is no room to admit a belt-tripper. 2. Where the first discharge is less than 20 ft. from loading point of the conveyor, a distance too short to admit a tripper. 3. When the conveyor is shorter than 50 ft. center to center. 4. Where separate spaced bins are used, instead of one continuous bin. 5. Where the conveyor is exposed to rain, snow or freezing.

**Table 9.—Capacities and Variable Dimensions of V-bucket, Gravity-discharge Machines**

(Link-Belt Co., Philadelphia)

| Size of Bucket, in. $L \times W$ | Capacity in Tons per Hour at 100 ft. per min. | | | | See Figs. 18 and 19 | | |

For either machine, these limits are not hard and fast, and between them there are chances to exercise personal preference or judgment. Both machines have been on the market for many years and have been standardized. There is no " universal " conveyor; for handling heavy or gritty ores, as in the Western smelters, or in conveying heavy tonnages of coal over long distances, as in by-product coke plants, a flight conveyor is not to be considered, but in many boiler houses it makes the best distributor, even though it requires more power. The older forms of flight conveyor were noisy, but modern roller-flight conveyors, or double-strand roller-chain conveyors, are by comparison almost noiseless. They are strong and rugged, easy to load and discharge, and will work under conditions and lack of care that would be harmful to belts. Some engineers have a prejudice against scraping the coal in a trough. It does consume more power, but it does not harm even anthracite. As to wear on the trough, the item of replacement is not an important one.

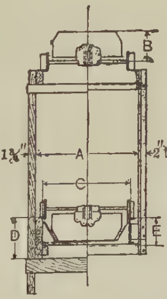

Fig. 20. Single Strand Flight Conveyor

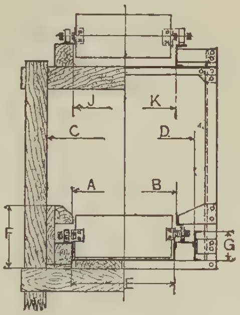

Fig. 21. Double Strand Roller Conveyor

**FLIGHT CONVEYORS FOR BOILER HOUSES.**—Two forms are in general use. Fig. 20 shows a single strand of chain carrying flights with supporting rollers. Fig. 21 shows flights fastened to two strands of chain with rollers mounted on the chain joints. The first is used for crushed coal; the other will carry any size of coal up to run-of-mine. Dimensions and capacities are given in Tables 11 and 12. All flights will carry the stated quantities of bituminous coal on the level, or on inclines up to 20 deg. For a slope of 25 deg., deduct 10%; for 30 deg., deduct 20%; for 35 deg., deduct 30%.

$$\text{The capacity in tons of coal per hour} = 0.36\,MT/S \quad . \quad . \quad . \quad . \quad . \quad [7]$$

**CHAIN PULLS AND HORSEPOWERS.**—The general formula for any ordinary flight conveyor, apron conveyor, bucket elevator or bucket carrier is

$$\text{Pull} = P = X + Y + Z, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [8]$$

where $X$ = pull to move the weight of material, coal, etc., on the loaded run; $Y$ = pull to move the conveyor parts on the loaded run; $Z$ = pull to move the conveyor parts on the empty run.

$X = WL(F \cos \alpha + \sin \alpha)$; $Y = W_1 L(f \cos \alpha + \sin \alpha)$; $Z = W_1 L(f \cos \alpha - \sin \alpha)$, where $W$ = weight of coal, etc., lb. per ft.; $W_1$ = weight of conveyor parts, lb. per ft.; $L$ = length of conveyor, ft.; $\alpha$ = angle of inclination from the horizontal; $F$ = coefficient of friction for the material (coal, etc.); $f$ = coefficient of friction of moving conveyor parts.

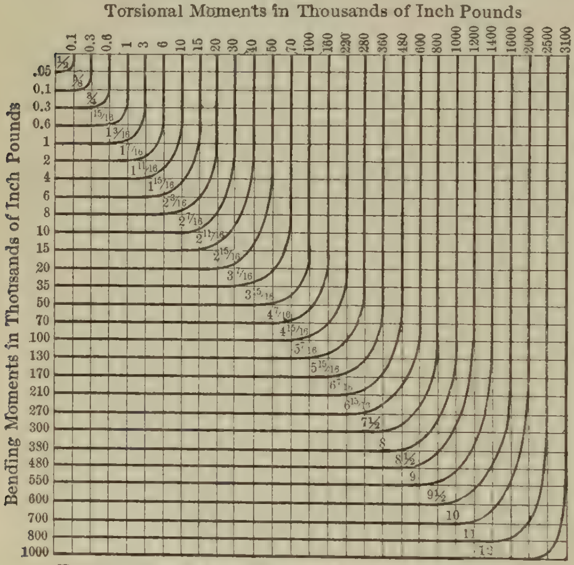

FIG. 22. Bending and Torsional Stress of Head-shafts

For anthracite, $F$ = 0.33; for bituminous coal, $F$ = 0.50. For conveyor parts, sliding in a trough or on tracks, $f$ = 0.33; for conveyor parts, rolling on tracks, $f = Nd \div D$, where $D$ = diameter of chain roller, in.; $d$ = size of hole in roller, in.; $N$ = factor determined by the kind of hole and the grade of lubrication. For a smooth hole, not lubricated, $N$ = 0.5; for a smooth hole, greased, $N$ = 0.33; for a bored hole, greased, $N$ = 0.25; for a bored hole, well oiled, $N$ = 0.20. For vertical lifts, $\cos \alpha = 0$; for horizontal runs, $\sin \alpha = 0$. For ordinary bucket carriers, apron conveyors, etc., where the material is carried, and not scraped, $F = f$.

If material is carried down hill or lowered, $\sin \alpha$ becomes negative and then

$$X = WL(F \cos \alpha - \sin \alpha);\ Y = W_1 L(f \cos \alpha - \sin \alpha);\ Z = W_1 L(f \cos \alpha + \sin \alpha).$$

For combined elevator conveyors of complicated path, make a diagram of the path, calculate the pull for each run separately, note it on the diagram with a plus sign if positive and with a minus sign if the pull is in the direction of motion of the machine. Add the several values, allowing at each turn, where pull is transmitted, 5% of the accumulated pull up to that point. Note $P$, the maximum pull where the chain enters the driving sprocket wheel, and $P_1$, the pull on the chain leaving the wheel. Then $P$ determines the stress in the chain, and $(P - P_1)$ is the torsional pull on the driving-wheel. From this

$$\text{Hp.} = T(P - P_1)/33{,}000 \quad \ldots\ldots\ldots \quad [9]$$

where $T$ = chain speed, ft. per min. For the size of the motor, increase horsepower by 10% for each pair of cast-tooth gears, and by 5% for each drive through belt, chain or cut-gears.

**SIZES OF SHAFTING FOR ELEVATORS AND CONVEYORS OF ALL KINDS.**—Head-shafts and important turn-shafts should be calculated for torsion and bending. From formula [9], $(P - P_1)$ is the torsional pull; this multiplied by the radius of the sprocket wheel gives the torsional moment in inch-pounds. The load which produces bending is the resultant of two forces. One of these is $(P - P_1)$; the other is the weight of the shaft, wheels and gear. In a vertical machine, the resultant is the algebraic sum of the forces. For other machines the weight of shaft, etc., is ignored, if it is proportionately small; otherwise the resultant is found by means of a diagram of forces. The shaft then may be considered as a beam supported by its bearings, and the bending moment in inch-pounds determined. Observing where the bending stress and the torsion stress act together on the same cross-section of the shaft, the shaft diameter may be obtained from the diagram, Fig. 22.

**CHAINS FOR FLIGHT CONVEYORS.**—Malleable-iron hook-joint chains are used for simple flight conveyors without rollers when the pull is not over 1500 lb. For roller flights, malleable-iron, closed-joint chains, or chains of the steel bar type are common. For double-strand conveyors with flights 20 × 10 in. or smaller, and of moderate length, malleable-iron roller-chains are used; for larger flights, and for heavy duty, steel bar-chains are better. These are made in pitches from 9 to 24 in. and of a strength to meet any service.

## 3. ASH HANDLING

**HANDLING ASHES IN BOILER HOUSES.**—For pneumatic system, see p. 23–67; for hydraulic methods, see p. 23–70; for skip hoists, see p. 23–50; for pivoted bucket carriers, see p. 23–50.

In small plants, ashes often are collected by hand car and taken to a waste dump, or discharged into a skip or elevator for storage in a bin. Ashes elevators which work only an hour or two per day are of the centrifugal discharge type (see p. 23–50) with a chain strong enough to withstand grit and corrosion. If the machine must work longer, it is better to use a slower speed elevator or a skip hoist. For handling large clinkers, old brick, soot and other boiler house refuse, a car and skip system is better than any bucket elevator. For high lifts a skip hoist is better under any conditions.

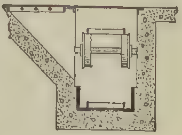

Fig. 23. Ashes Conveyor

A simple ashes conveyor used in some small boiler houses is shown in Fig. 23. A wide malleable-iron chain runs at about 5 ft. per min. in a heavy cast-iron trough and partly drags, partly carries the ashes to the foot of an elevator. It is cheap, requires no lubrication, and lasts long enough to pay for itself in some places.

## 4. ELEVATORS FOR MATERIALS OTHER THAN COAL

It is necessary to consider whether material to be handled is fine or in large pieces, abrasive or non-abrasive, friable or non-friable, wet or dry, whether or not it must be handled at slow speed. It is not possible to give exact rules, but for most cases the following is useful:

1. Ashes, crushed ores, small coal, foundry sand, dry clay, gypsum, acid phosphate and similar materials. Use centrifugal discharge elevators with malleable-iron buckets on single-strand closed-joint, or steel-bushed malleable-iron chain.

2. Grains, feeds, and other free-flowing materials. Use centrifugal discharge elevators with chains lighter than those in (1), or rubber belts, with malleable-iron or sheet-steel buckets.

3. Cement, crushed coal, coke, slag, ores, glass house cullet and other material, not too large, which should be handled at relatively slow speeds. Use single-strand continuous-bucket elevators with steel buckets on closed-joint or steel-bushed malleable-iron chains. These elevators are vertical, or nearly so, and have a boot and casing.

4. For materials in (3), handled in large quantities or to high lifts, use double-strand continuous-bucket elevators with steel buckets on steel chains.

5. Heavy coarse material, ores, crushed stone, gravel, and rock which cannot be picked up in a boot. Use inclined continuous-bucket elevators with one or two strands of chain or a rubber belt.

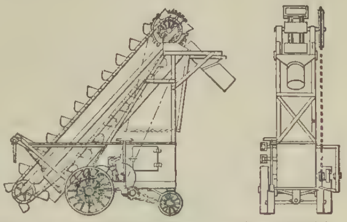

Fig. 24. Self-propelled Loading Machine

Elevators for handling coal in boiler houses and for many other materials have been classified and standardized by manufacturers [44], [50] (see p. 23–81), and other makers of conveying machinery, whose catalogs give dimensions, capacities, speeds, power required, and details of casings, boots, etc. For belt elevators, see handbooks issued by rubber belt makers, Goodyear Rubber Co., Akron, O.; Goodrich Rubber Co., Akron, O.; Manhattan Rubber Co., Passaic, N. J., and others.

**PORTABLE ELEVATORS OR LOADERS** are bucket elevators with a motor or gasoline engine mounted on wheels or caterpillar treads, and arranged to pick up their load at ground level and deliver it to wagons or trucks through a chute, screen or short belt conveyor. Some loaders for hard coal, coke, or excavated gravel have shaking screens. In coal yards, they save time and labor and reduce cost of handling by keeping trucks at work. A man will shovel a ton of coal from ground to wagon in 20 min.; a loader in 3 min. or less. Four men load a 5-ton truck by hand in 30 min.; one man with a loader in 5 min. The system of using loaders in connection with ground storage is preferred by many to storage in overhead bins with chutes to wagons. First cost and depreciation are less and there is less machinery to maintain. For large capacities, or where a machine handles sand, stone or gravel, a self-propelled machine, Fig. 24, is an advantage. The loader backs into the pile by its own power, which is quicker and easier than breaking down the pile by hand. Loaders that work on roads or in yards with soft floors should have caterpillar treads.

Portable elevators are made by manufacturers [9], [36], [50] (see p. 23–81), and others. These machines in modified form excavate earth, dig trenches for pipe lines, remove snow from city streets. A development by Barber-Greene is a portable road building machine that travels under its own power, picks up sand and gravel, mixes it with bituminous binder, spreads, tamps and levels it to make a finished road at the rate of 1 mi. per hr.

**VIBRATING CONVEYORS,** mounted on roller races for use in mines are described below. Similar conveyors with the trough mounted on spring legs (Link-Belt Co.) are used for sugar and other materials not easily handled by screw, flight or apron conveyors.

Vibrating pipe conveyors made by Traylor Vibrator Co., Denver, Colo., are used to convey roasted ores, sintered concentrates and other hot, dusty and gritty materials. The pipes are 10 to 26 in. diam., hung by flexible suspension from above. Vibrating units are clamped to the pipe at intervals, each consisting of an armature and a stator supplied with alternating current. At 60 cycles per sec. the armature is attracted 3600 times per min. against the flexure of powerful bar springs. The inertia of heavy weights attached to the frame causes the pipe and armature to vibrate in unison. The plane of vibration is inclined to the axis of the pipe, and the material receives a component of motion, which moves it through the pipe. See A. F. Beasley, *Engg. and Min. Jour.*, March 24, 1930.

**The Redler Conveyor** (Stephens-Adamson Mfg. Co.) consists of a flexible chain or wire rope carrying pusher bars or links at short intervals. These move in a closed box, imbedded in the material conveyed. By a proper arrangement of turns, horizontal and vertical runs can be combined, and the machine acts both as elevator and conveyor. Moving parts do not completely fill the cross-section of the box and the conveyor is said to be free from danger of overloading.

## 5. COAL CONVEYING IN THE MINE

Coal conveying in a mine starts at the working face. Coal which has been shot down can be loaded by hand on a low portable scraper, shaker or belt conveyor, discharging to a longer conveyor or a mine car. Fig. 25 shows a scraper conveyor, comprising a drive section with motor and gearing, a foot section with take-up, and intermediate cross-sections 6 ft. long, bolted together. Wide link chain runs in a trough 14 in. high, Fig. 26. Belt conveyors are similar in cross-section. Shaker conveyors, Fig. 27, have troughs in sections bolted together. Each section rests on a pair of rollers in curved pieces of track, shaped to give a jumping motion to the coal when the assembled length is reciprocated by a crank at the driving end. Speed and throw of crank are varied to suit length of travel, slope, and kind of coal.

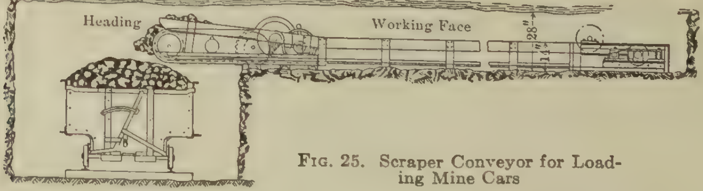

Fig. 25. Scraper Conveyor for Loading Mine Cars

Another type to make loading of mine cars easier is a chain conveyor with a low end, an inclined portion, and a horizontal top portion extending over one or more mine cars, all mounted on wheels. Other machines, to displace hand shoveling altogether are made by Jeffrey Mfg. Co., Columbus, O. A shovel machine (Myers-Whaley Co., Knoxville, Tenn.) thrusts a scoop under the loose coal, lifts it and tips it backwards into a conveyor discharging into the mine car. A loader made by Joy Machine Co., Pittsburgh, Pa., has pickpointed arms which dig into the coal and pull it into path of the conveyor chain. Several machines with wire rope drum and a scraper that drags the coal from the working face are made by manufacturers [34], [42], [86] (see p. 23–81).

U. S. Bureau of Mines, *Bull.* 343, Dec., 1930, describes and illustrates these machines. For English machines, see *Iron and Coal Trade Rev.*, No. 123, 1931. For German machines, see *Fördertechnik*, Jan. 16, March 13, May 8, July 3 & 31, Oct. 23, 1931. For a flexible conveyor for long face mining, see *Coal Age*, May 7, 1925.

**COAL CONVEYING BY MINE CAR HAULAGE.**—Robert Peele (Mining Engineers' Handbook) says: Locomotive haulage is justified at mines with easy track grades and large output. Compared with haulage by animals, the high speed, large tonnage per trip, and few men required, may balance the larger interest and depreciation charges. Compared with rope haulage, especially if there are branches or many curves, it is more flexible and easier to extend or maintain. It requires less head-room, heavier rails and easier curves than animal haulage, but cannot compete with it on thick seams in daily output of less than about 175 net ton-miles on grades below 1.25%, nor with rope haulage on grades averaging 4% against or 5% with loads.

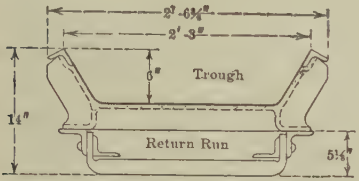

FIG. 26. Cross-section of Scraper Conveyor

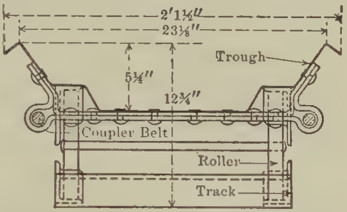

FIG. 27. Cross-section of Shaker Conveyor

**Gasoline Locomotives** have the flexibility of steam locomotives in radius of travel, and for mining work are geared for speeds of 3 to 12 miles per hr. They have no open fire, consume no fuel when idle, and are less dangerous than steam locomotives in gaseous mines. Exhaust gases and cost of gasoline are factors to consider.

**Compressed-air Locomotives** are flexible in operation within the radius of travel from charging stations for which they are designed, require no fire, do not spark nor emit noxious exhaust, but aid ventilation and are the safest type for gaseous, dry-timbered or poorly ventilated workings.

**Electric Storage-battery Locomotives** are flexible, cheaper to install than trolley or air locomotives, simple to operate and safer than any other type except compressed-air. They are suitable for short hauls, in temporary workings, as in gathering, or for infrequent long hauls where trolley lines are not warranted or where low-roofed wet workings make them dangerous. Grades must be easy.

**Electric Trolley Locomotives** are the prevalent types in mines. They are compact, simple to operate at high efficiency and usually have lowest power cost of all types. Disadvantages are: Cost and danger of trolley circuit; danger of sparking at commutator or trolley wheel; necessity of wired and bonded track.

**Rope Haulage** conditions are large tonnage and grades which make locomotive haulage inefficient. Straight haulways and uniform grades are desirable but not necessary. See Rope Haulage, p, 23–13.

**UNDERGROUND CONVEYING BY BELT CONVEYOR.**—A belt conveyor system may handle large quantities of materials in mines at a lower cost than any system of haulage. At the Colonial mines of H. C. Frick Coke Co., near Brownsville, Pa., trains of cars in the mine are turned over in a rotary dumper; the coal falls into a bin and is fed by feeders to a 60-in. belt which delivers to a series of 19 48-in. belts run at 500 ft. per min., and of lengths from 321 to 2439 ft. The total run is 4 $1/2$ miles; the total lift is 357 ft.

The system was planned and installed after the estimate had shown a probable saving of 3 cts. per ton, 10,000 tons a day, based on the following comparisons between the belt system and haulage by electric locomotive: 1. First cost, belts 25% less. 2. Depreciation, belts 15% more. 3. Cost of power, belts 100% more. 4. Cost of labor, belts, 50% less. The belt system was started in 1924. Up to July, 1932, it had carried over 25,000,000 tons of coal, and 8 of the original belts were still in use. Records and tests have shown the cost of power for the belt system to be less than $1/2$ of that estimated, the saving in labor to be greater than estimated and saving in cost of conveying to be over 3 cts. per ton. For a description of this system, see *Coal Age*, Dec. 25, 1924; F. V. Hetzel, Belt Conveyors and Belt Elevators, p. 106. A belt conveyor similar to the above is used at the Palmer mines of H. C. Frick Coke Co. It has 12 belts with a total length of travel of over 3 miles.

For uses of belt conveyors in and about mines, see catalogs of manufacturers [50], [77], [85] (see p. 23–81).

**RETARDING CONVEYORS.**—In parts of West Virginia and Kentucky, coal veins are on the hills and railroad tracks in the valley. An old way to get coal down is in coupled mine cars lowered down the slope by a tail rope. A broken car coupling or rope may cause a runaway resulting in great damage or loss of life. Coal sometimes is lowered in a large skip (monitor or gunboat) but unless it is shipped as run-of-mine, breakage due to filling and emptying the skip is objectionable. Wire rope tramways have been used for capacities of a few hundred tons per day (see p. 23–14). For larger capacities, retarding conveyors are used.

**The Wire Rope Retarder**, Fig. 28 (Jeffrey Mfg. Co., Columbus, O.) comprises an endless wire rope to which 12 in. diam. cast-iron discs are clamped at intervals of 3 or 4 ft. On the carrying (lower) run the discs travel in a V-shaped trough with rounded bottom. On the return they run in a small guide trough. The rope, $^7/_8$ to $1\,^1/_8$-in., generally is made with 6 flattened strands (see p. 6–40) arranged alternately, regular lay and lang lay so that the rope does not twist or rotate. The ends are joined in a split clamp disc. Rope retarders can be used on any slope up to 35 deg. and up to 1000 ft. long. The best slope for soft coal is about 26 deg. For slopes over 30 deg., hinged baffle-boards over the trough stop lumps if they start to avalanche. A straight run is preferable, but if slope must change from steep to flat, a large radius curve (1000 ft.) should be made in the trough, or one conveyor must be made to discharge into another. As the wire rope is submerged in coal, wheels or tracks cannot be used to hold the rope down. At terminals, the rope runs over toothed wheels. On all but flat slopes, brakes prevent the conveyor drifting when power is off. On steep slopes a hand-operated brake also is used. Rope retarders have been used for 50 years or more. When properly designed and built they are good and relatively inexpensive. Carrying capacity is 100 tons to 200 tons per hr.

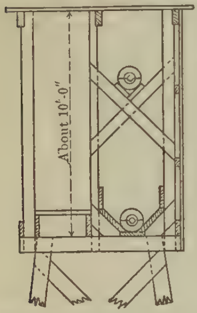

Fig. 28. Wire Rope Retarder

**Chain and Flight Retarding Conveyors** consist of two strands of steel roller chain attached to ends of steel flights, running in a steel trough. The chains roll on tracks and the path of the conveyor can be made to suit the slope and contour of the ground. Fig. 21 shows a cross-section. A 36 × 12 in. flight will carry 360 tons per hr. at 100 ft. per min. Some retarders have 48 × 12-in. or 60 × 16-in. flights for large carrying capacity. Fig. 29 shows the upper end of a retarding conveyor where a shaking screen separates the fines before the coal goes to the picking bands. With such an arrangement, refuse is thrown out on the slope of the hill.

**CLEANING AND SIZING OF BITUMINOUS COAL.**—The handling of bituminous coal for cleaning and sizing in one modern tipple may be described as follows: The tipple building is a steel structure spanning 5 railroad, and 2 larry tracks, that run to coke ovens. Coal runs from lower end of retarding conveyor over a bar screen which removes slack, then over a double deck shaking screen which takes out more slack and separates the rest into lump, egg and nut. These sizes discharge separately to three steel apron conveyors which are placed parallel to the railroad tracks and located directly over them. For about 30 ft. the apron conveyors are horizontal. Men on each side pick out refuse. For the remainder of their length, conveyors are on hinged booms, which by electric hoists, can be lowered or raised so that coal is loaded into railroad cars without much breakage. When booms are horizontal, coal can be discharged into mixing chutes, arranged so that lump and egg, for instance, or egg and nut, can be loaded into cars. Refuse picked out of the coal is dropped into vertical chutes, whence it passes into conveyors under tipple floor and into a car for disposal. Everything below nut size from shakers and bar-screen is conveyed to a screen house over the larry tracks. A rotary screen takes out the pea size and drops it into a bin for shipment by car or truck. Slack falls into a bin, and either is taken in larrys to coke ovens or conveyed across the tipple for mixing with any of the larger sizes on the railroad loading track. Fig. 30 shows the arrangement of loading boom and picking table in a small tipple.

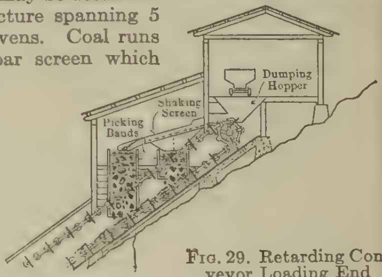

Fig. 29. Retarding Conveyor Loading End

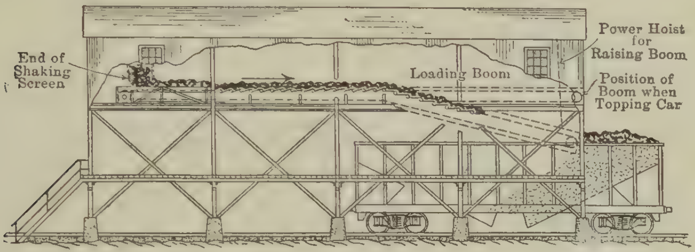
The Knox-GON swiveling loading boom (Link Belt Co.) has a frame pivoted at the receiving end, and is placed over the center line between two tracks. It can be swung to serve gondolas on either track or to discharge to a Manierre type loader for loading box cars on either track. This machine (Manierre Engg. Co., Milwaukee) has a short belt or apron conveyor mounted on a hinged and jointed boom adjustable to various angles. It is capable of being moved into working position through a car door, or swung out to give car clearance. It will handle any kind and size of lump or fine material and deposit it in either end of a box car with a minimum of breakage.



End of Shaking Screen
Loading Boom
Power Hoist for Raising Boom
Position of Boom when Topping Car

FIG. 30. Picking Table and Loading Boom in Coal Tipple

The rescreening loading boom (Link Belt Co.) has two chains with cross bars running in a trough with screen bars in the bottom. Its advantages are lighter construction, shorter boom and less drop of coal at delivery end.

# BELT CONVEYORS

For fundamentals of design and operation, see F. V. Hetzel, Belt Conveyors and Belt Elevators (John Wiley & Sons). In its simplest form a belt conveyor comprises two end pulleys, a moving belt, and idlers to support the belt. The lower idlers have flat-faced rolls; the upper or carrying idlers generally are arranged to curve or trough the belt to make it carry more and avoid risk of spill. There is not much difference between 3- and 5-roll troughing idlers in carrying capacity. Three-roll idlers cost less, have fewer bearings, lubrication is more certain. The best troughing idlers have ball or roller bearings; the saving of power, reduced cost of maintenance and longer life of belt often pay for the extra cost of the improved idlers. On grain conveyor belts, the best practice is to run the belt nearly flat with concentrator or "tuck-up" idlers at intervals to give a slight troughing.

Troughing idlers are spaced 4 to 5 $1/2$ ft. apart on narrow belts, according to weight of material carried; on wide belts, 3 to 4 ft. apart. Return idlers are spaced 9 or 10 ft. apart.

For detailed information about belt idlers and other parts, see catalogs No. 1615, Link-Belt Co., Chicago; No. 82, Robins Conveying Belt Co., New York; No. 30, Stephens-Adamson Mfg. Co., Aurora, Ill., and other manufacturers of conveying machinery.

**THE CONVEYOR BELT** may be of solid woven fabric, or of cotton duck with the plies stitched together. Both kinds are impregnated with oils or compounds to resist moisture. Rubber belts, however, are in more general use. They are built up with layers of cotton duck cemented together by rubber compounds, and then vulcanized. Lengthwise threads of the cotton duck are heavier than crosswise to give tensile strength with flexibility for troughing. An extra thickness or cover of rubber on carrying side of the belt resists abrasion and increases its life. For crushed coal, the cover may be $1/16$ in. thick, but for run-of-mine coal and abrasive ores a thicker cover is required to avoid puncture by sharp pieces, and to resist wear occasioned by making material at the loading point acquire the belt velocity.

**CARRYING CAPACITIES OF BELT CONVEYORS** in tons of coal per hour for troughed belts are given in Table 1, which is based on formula, cu. ft. per hr. at 100 ft. per min. = $3.2W^2$, where $W$ = width of belt, in. Belts carefully loaded with run-of-mine coal can run 500 ft. per min.; higher speeds in Table 1 refer to crushed coal. If material is not too lumpy and if feed is steady and continuous, belts wider than 18 in. can be loaded to a greater capacity, *viz.*, 24 in., 5% more; 30 in., 10%; 48 in., 16%; 60 in. 20%.

On narrow belts, a relatively greater percentage of lumps comes in contact with the belt surface in loading. Wear from abrasion in loading is proportional to speed of belt. Hence, it is injurious to run narrow belts at high speeds. At the same time, part of the efficiency of the belt as a conveyor is due to the ability to run faster than a chain conveyor, whose speed seldom exceeds 200 ft. per min. At speeds much lower than that a belt is not so economical in handling bulk materials, although it may be preferred for other reasons. Width of the belt depends on lumpiness of material carried. Table 2 gives values ordinarily considered safe and proper.

**HORSEPOWER OF BELT CONVEYORS.**—A formula based on tests of belt conveyors (Goodyear Rubber Co., 1930) is in three parts.

$$\text{Hp. of empty conveyors} = C(L + L_0)(0.03\,QS)/990 \quad [1]$$

$$\text{Hp. to carry tonnage on a level} = C(L + L_0)T/990. \quad [2]$$

$$\text{Hp. to raise tonnage} = +(TH/990)\text{; to lower tonnage} = -\ (TH/990) \quad [3]$$

The algebraic sum of the three items gives horsepower at head pulley; $C$ = a friction factor depending on kind of idlers used, $=0.05$ for plain bearings, grease lubricated; $=0.03$ for ordinary ball or roller bearings, grease lubricated; $=0.022$ for high-grade ball or roller-bearings, pressure lubricated; $L$ = length of conveyor, ft., center to center; $L_0$ = arbitrary length factor, depending on grade of equipment used, $=100$ where $C = 0.05$; $=150$ where $C = 0.03$; $=200$ where $C = 0.022$. $Q$ = (weight of moving parts of idlers + weight of belt reduced to lb. per ft. of center to center length of conveyors), (see Table 3); $S$ = belt speed, ft. per min.; $T$ = tons of material per hr.; $H$ = height, ft., through which material is raised or lowered.

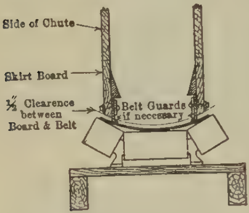


FIG. 1. Skirt Board Construction

If a tripper is used, add 1 Hp. for narrow belts, and up to 3 Hp. for wide belts. To determine size of motor, add 3% to 5% for each belt drive, chain drive or gear reduction.

**BELT THICKNESS.**—In general, for durability and long life, tension in a rubber or cotton belt should not exceed 24 lb. per in. of width per ply of thickness, if duck is the usual 28-oz. duck. In a belt conveyor, this 24 lb. cannot all be used to move the loaded belt. Some of it must be used to supply enough tension to prevent slip on the drive pulley. This tension is applied by the take-up. The smaller the arc of wrap on the drive pulley and the lower the coefficient of friction between belt and pulley, the greater must be the tension. By increasing angle of wrap and lagging drive pulley, more of the strength of the belt can be usefully employed.

After calculating horsepower by method given above, the number of plies of belt to move the loaded conveyor may be found by

$$N = \text{number of plies} = \text{Hp.} \times 33{,}000/SWP, \quad [4]$$

where $S$ = belt speed, ft. per min.; $W$ = belt width, in.; $P$ = useful net tension per inch of width per ply of thickness. The relation between belt tension, belt velocity and horsepower is given on p. 24–14. The value of the coefficient of friction $f$ in the fundamental formula there given may be taken as $f = 0.30$ for conveyor belt on bare iron pulleys, and $f = 0.34$ for belt on lagged pulleys. Values of $P$ may be taken as follows: 180° wrap on iron pulley, $P$ = 14 lb.; 180° wrap on lagged pulley, $P$ = 16 lb.; 240° wrap on lagged pulley, $P$ = 18 lb.; 420° wrap on 2 lagged pulleys geared together, $P$ = 24 lb.

Table 1.—Tons (2000 Lb.) of Coal per Hour at Various Belt Speeds

| Width of Belt, in. $W$ | Belt Speed, ft. per min. = $S$ | | Width of Belt, in. $W$ | Belt Speed, ft. per min. = $S$ | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | 300 | 350 | | 300 | 350 | 400 | 450 | 500 | 550 | 600 |
| 12 | 34 | ... | 24 | 139 | 162 | 184 | ..... | ..... | ..... | ..... |
| 14 | 49 | ... | 30 | 216 | 252 | 288 | 324 | ..... | ..... | ..... |
| 16 | 62 | ... | 36 | 311 | 363 | 414 | 466 | 518 | ..... | ..... |
| 18 | 80 | 92 | 42 | 423 | 493 | 564 | 635 | 705 | 775 | ..... |
| 20 | 96 | 112 | 48 | 552 | 644 | 737 | 830 | 920 | 1013 | 1105 |

Table 2.—Maximum Size of Material to Give Capacities in Table 1

| Size of Material, in. | Belt Width, in. | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | 14 | 16 | 18 | 20 | 24 | 30 | 36 | 42 | 48 |
| 90% of mixture not over | 2 | 2 1/2 | 3 | 3 1/2 | 4 1/2 | 6 | 7 1/2 | 9 | 10 1/2 |
| 10% " " " " | 3 | 4 | 5 | 6 | 8 | 11 | 14 | 17 | 20 |

Table 3.—Values of Factor $Q$ in Belt Conveyor Horsepower Formula

| | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Width, in. .......... | 12 | 14 | 16 | 18 | 20 | 24 | 30 | 36 | 42 | 48 | 54 | 60 |
| $Q$ ................ | 15 | 16 | 17.5 | 19 | 21 | 25 | 32 | 40 | 49 | 59 | 69 | 81 |

If the belt is made of 32-oz. duck, values of $P$ may be multiplied by 1.125. Horsepower may be calculated from the fundamental formula for belt tension, *viz.*, Hp. $= PV/33{,}000$, where $P$ = net effective tension in belt $= (T_1 - T_2)$, the tension in the tight and slack sides, respectively; $V$ = velocity, ft. per min.

Values of $N$ obtained from the formula should be compared with tables of maximum and minimum thicknesses of belts as given in handbooks of belt makers. If the belt is too thin it will deflect too much; if too thick, it will not trough properly.

Rubber belts are made in different grades, differing as to weight of duck, quality of "friction" used to cement plies together, and thickness and quality of rubber covers. For detailed information, see F. V. Hetzel, Belt Conveyors and Belt Elevators, pp. 41, 110. Goodyear's 1930 Handbook gives considerable detailed information concerning belts, tandem drives, stresses in inclined conveyors, etc. See also Goodrich's Manual of Belt Practice, No. 2800.

**DIAMETER OF BELT PULLEYS.**—The larger the pulley, the less the stretching of the rubber "friction," or of the stitching which holds the plies of the belt together, and the longer the belt will last. The diameter of driving pulleys in inches should be at least five times the number of plies in the belt. The diameter of foot pulleys and snub pulleys should be four times the number of plies, and of tandem pulleys, geared together, driving thick belts with heavy rubber covers, at least six times the number of plies.

**LOADING BELTS.**—To reduce the wear on the belt surface, the material should be fed by a chute of such length and slope as will give to the material the velocity of the belt, if possible. To prevent scatter, and to pile the load properly, skirt-boards 5 to 7 ft. long are used. They must be carefully designed. If not well supported they may sag and cut the belt. Fig. 1 shows the usual construction in wood.

**DISCHARGE FROM BELT CONVEYORS.**—The simplest belt conveyor discharges over the head-pulley, as in Fig. 2. For intermediate discharge at one or more points, fixed trippers may be used, as in Fig. 3, but they double or triple the wear on the belt surface whenever they feed material back on the belt, and by repeated reverse bending over pulleys they tend to separate the plies of the belt. For most conditions of intermediate discharge, a traveling or movable tripper, Fig. 4, is preferable. Some materials, like foundry sand or wood chips, can be carried on flat belts, and at slow speeds the discharge can be divided at several intermediate points by "strike-off" boards set at various positions above the belt, or all can be thrown off at any point if the boards are hinged so as to swing into and out of position. This method is not good with lumpy material.

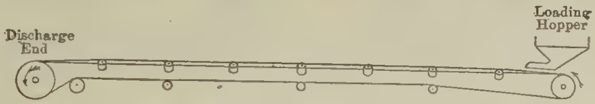

FIG. 2. Belt Conveyor Discharging Over Head Pulley

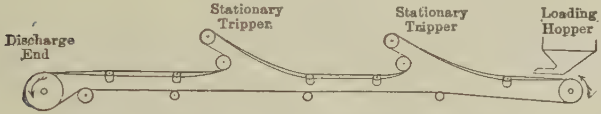

FIG. 3. Belt Conveyor with Stationary Trippers

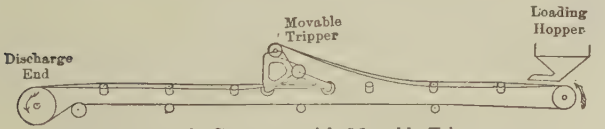

FIG. 4. Belt Conveyor with Movable Trippers

**INCLINED BELTS.**—With uniform feed, fine coal may be carried on a belt at an angle from the horizontal of 22 deg.; but when mixed with lumps, at an angle of not over 20 deg. Run-of-mine coal, coal and coke can be carried at an angle of not over 18 deg., crushed stone and ore, at not over 18 deg., and tempered foundry sand at not over 24 deg. On the other hand, numerous substances under certain conditions can be carried at not over 15 deg.

**ADVANTAGES OF BELT CONVEYOR.**—1. Low power consumption. 2. Noiseless operation. 3. Adaptable to all sorts of material. 4. Suitable for high capacities and long distances beyond the range of other conveyors. 5. Simplicity of construction.

**LIMITATIONS OF BELT CONVEYOR.**—Some comparative disadvantages are stated on page 23–61. The belt is the expensive item and must be protected from the following sources of injury: 1. Poor arrangement of feed. 2. Chute or skirt-board sagging on belt. 3. Lumps falling on return belt and jamming between foot pulley and belt. 4. Belt running crooked and fraying the edges. 5. Oil or grease getting on rubber belt. 6. Continued exposure to great heat or cold, or direct sunlight.

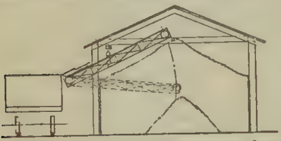

FIG. 5. Portable Conveyor for Car Unloading

When belts are inclined, especially at or near the maximum angle, there is a shift or slip of material in passing over each troughing idler. This adds to the wear on the carrying surface, and with gritty materials it may be serious. Short belts, steeply inclined, are apt to be short-lived under such conditions, because the wear from the pick-up at the loading point is already large, due to the fact that each foot of belt passes the loading point frequently. In long belts the wear from pick-up is distributed over a greater amount of belt surface and the bending over pulleys does not occur so often. Hence long belts last proportionately longer than short belts.

**STANDARD BELT CONVEYORS,** 16 to 48 in. wide for various lengths and capacities are shown in catalogs of manufacturers [44], [50], [85] (see p. 23–81), and other makers of conveying machinery. For many conditions of ordinary service, time and expense can be saved by buying a conveyor from a catalog rather than designing one.

**Sectional Belt Conveyors** 18 and 24 in. wide (Barber-Greene Co.) consist of standard drive and take-up groups with machinery parts mounted on steel frames. Conveyor length is made up of light steel frames of various standard lengths, which, with belts, idlers and guards weigh not more than 60 lb. per ft. They will span 25 to 50 ft. in the clear.

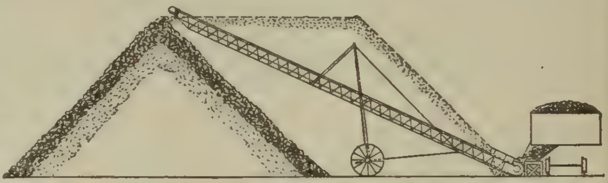

FIG. 6. Portable Conveyor for Piling

**Portable Conveyors** of the same light construction, listed by the same makers, are used to receive concrete from mixers and deliver it to forms in building construction. By having one conveyor discharge to the next, concrete can be distributed over large areas. In some cases, 15 conveyors have been used for a distance of 500 ft. or more. The 24-in. belt runs over 2-roll idlers to form a deep trough. A flexible scraper under each head pulley removes concrete from the belt. Frames are made up to 50 ft. long and are mounted on large caster wheels. For handling concrete on belt conveyors, see *Trans.* A.S.M.E., MH–52–10, 1930.

Other portable belt conveyors are made by the companies above named and also by manufacturers [33], [72], [77], [82] (see p. 23–81). Fig. 5 shows one which stores in a shed, material shoveled over side of a car. The frame is hung from a chain block and trolley on an overhead track that runs the length of the shed. Motor- or gasoline-driven conveyors on wheeled frames, Fig. 6, with 12-, 14- or 16-in. belts on frames 20 to 40 ft. long, will receive material from bottom-dump or side-dump cars and form storage piles or deliver to bins or wagons. Several machines can be placed in tandem to deliver to a distance, or a high pile can be formed by arranging machines as in Fig. 7. These machines are light, a 16 in. × 30 ft. size weighing less than a ton. Heavy machines of this type are made by Barber-Greene Co., with 18- or 24-in. belts on frames up to 60 ft. long, with a hand-power hoist for adjusting height of boom.

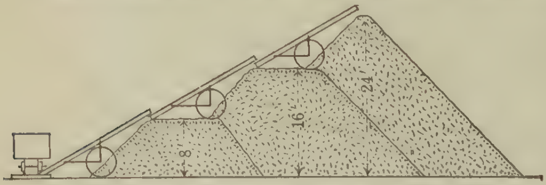

FIG. 7. Portable Conveyors Arranged for High Piling

**CAR LOADER BELTS.**—Short belt conveyors mounted on wheeled frames easily handled by one man, and run at 1200 ft. per min. or more will throw fine material a distance of 15 to 20 ft. The machine is placed in position at door of a box car, receives material from a chute, throws it into a pile at each end of the car and distributes it for proper loading. It saves the labor of several men. Loaders of this type are built by manufacturers [9], [50], [85] (see p. 23–81).

**CAR UNLOADER BELTS** (Barber-Greene) are mounted on a shallow steel frame, 4 or 5 in. deep, that can be laid across a track above the rails, or in a shallow pit below them, to receive discharge from a drop-bottom car. They are used for free-flowing materials without lumps. The service is severe, but the car can be unloaded anywhere on the track and a deep pit is unnecessary.

**WEIGHING ON BELT CONVEYORS.**—The Merrick Weightometer (Merrick Scale Mfg. Co., Passaic, N. J.) for weighing material in transit consists of: 1. A part of the upper run of the belt suspended from counterbalanced weighing levers. 2. A totalizer driven by the moving belt which continuously multiplies weight by travel to give tonnage passing over the conveyor. This is recorded on a counting machine or chart recorder.

**STEEL BELTS.**—The Sandvik belt (Sandvik Steel, Inc., New York) is a tempered, polished, cold-rolled steel band, about $^1/_{32}$ in. thick, made up to 32 in. wide and up to 375 ft. long. It runs flat over rollers, spaced 6 to 12 ft., or slides on wooden strips. These belts handle clinker, phosphate rock, sugar, clay, foundry sand and similar wet, sticky mixtures that do not discharge clean from fabric or rubber belts. They discharge either over the head pulley or by scrapers over the belts. The scraper is simple, cheap, and works well with materials that cannot be discharged cleanly by a belt tripper. The belts are light, run quietly, and when supported on rollers are said to take less power than rubber belts on troughing idlers. Belts wider than 32 in. can be made by a method of longitudinal jointing.

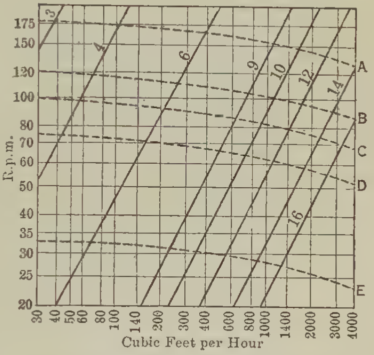

Fig. 1. Capacities of Screw Conveyors

**STEEL MESH BELTS** are used for conveying through acid or alkaline baths, chemical solutions, and scalding tanks, and in processes of drying, baking, annealing, spraying, etc., for which fabric belts would be unsuited. They are made in the U. S. by Cambridge Wire Cloth Co., Cambridge, Md., and Wickwire-Spencer Steel Co., New York. They consist of woven wire mesh, with or without edge reinforcement, or of coils of wire interlocked and flattened. Sometimes the coils are joined over wire rods which may be bent at the ends to form a protective edge or border. These belts can be made of copper, brass or the various alloys which impart strength or resist heat, corrosion, or the action of chemicals. They can be made with steel plate selvages or partitions that will bend around driving drums. Belts can be woven up to 12 ft. wide. Those made for lehrs and annealing ovens will work regularly in temperatures over 1000° F.

**LONG DISTANCE CONVEYING BY BELT.**—See p. 23–20 and p. 23–59. For a recent installation (Jeffrey Mfg. Co.) of long, wide belts of large carrying capacity, see *Engg. News-Record*, Aug. 1, 1935.

## SCREW CONVEYORS

Screw conveyors consist of a helical blade of metal fastened to a central pipe or shaft, and set in a trough or box. The blade generally is of steel plate, but depending on service and nature of material handled, it can be cast iron, cast steel or an alloy that resists corrosion and oxidation. The trough generally is U- or V-shaped with a rounded bottom. Some materials can be conveyed through a round pipe if the length is short enough to permit the screw conveyor bearings to be kept outside the pipe.

Bearings are of various kinds, babbitt, bronze, chilled cast iron, hardwood. Success with screw conveyors often depends on using the proper kind of hanger bearings and the right kind of trough. It is advisable to consult the makers on these points.

**CONVEYING CAPACITIES.**—Fig. 1 shows curves developed by Link-Belt Co., Chicago, for capacities of screw conveyors. Diagonals 3, 4, 6, etc., are diameters of screw, in. Curves *A*, *B*, *C*, etc., are advisable speed limits, r.p.m., but rating should be multiplied by a capacity factor *X*, given on p.23–66.

**Class 1.**—Dry, free-flowing, not gritty; as grain, malt, flour, meal, pulverized coal; advisable speeds not beyond curve *A*; $X = 1.00$.

**Class 2.**—Shelled corn, clean cotton seed, fine coal, crushed ice, pulverized minerals that are not abrasive; advisable speeds not beyond curve *B*.; $X = 0.75$.

**Class 3.**—Wet malt, starch, sawdust, ground cork, carbon black, dry paper pulp stock, non-abrasive minerals, with occasional lumps (not over 25%) of size not over $^1/_8$ diameter of screw; advisable speeds not beyond curve *C*; $X = 0.66$ to $0.75$.

**Class 4.**—Damp, trashy cotton seed, dry clay, raw sugar, foundry sand, fertilizers, crushed gypsum, lime, and other abrasive materials with lumps (not over 50%) of size not over $^1/_6$ diameter of screw; advisable speeds not beyond curve *D*; $X = 0.50$ to $0.66$.

**Class 5.**—Very gritty materials, as ashes, wet or dry, silica sand, pulverized flint or quartz, flue dust, fly ash; advisable speeds not beyond curve *E*; $X = 0.30$ or less.

The capacity factor *X* refers to screw conveyors with intermediate hanger bearings. If conveyor is short, has no hanger bearings, and is properly fed, capacity may be 50% greater than use of the factor would indicate.

Screw conveyors at slopes up to 10° or 15° have about the same capacity as level conveyors. At greater slopes, capacity tends to fall off, but for such conditions, screws with short-pitch flights can be used. Screws at steeper angles should be referred to the makers. Vertical screws, run at the proper speed and properly fed, will elevate ground cork and some other light materials in closed pipes. In "batching" plants that serve concrete mixers, Link-Belt vertical screws have been used to elevate cement 20 or 30 ft. They require more power than a bucket elevator and are apt to get out of order from cement working into the step bearing. The advantage is that they are light and portable.

**HORSEPOWER OF SCREW CONVEYORS.**—If a screw conveyor is crooked and out of line, if speed is excessive, if hangers and bearings are not suited to the work, if discharge outlets choke, then the power consumed cannot be estimated. For screws working under proper conditions, Link-Belt Co. gives the following general formula:

$$\text{Hp.} = 1 + (ALN + CWLF)/1{,}000{,}000 \quad . \quad . \quad . \quad . \quad . \quad [1]$$

where $L$ = length of conveyor, ft.; $N$ = r.p.m. of screw; $C$ = cu. ft. conveyed per hr.; $W$ = weight of material, lb. per cu. ft.; $A$ and $F$ are factors. For conveyors with lubricated bearings, values of $A$ are as follows:

| Diam. of screw, in. | 3 | 4 | 6 | 9 | 10 | 12 | 14 | 16 |
|---|---|---|---|---|---|---|---|---|
| *A* | 15 | 21 | 33 | 54 | 66 | 96 | 135 | 186 |

For bearings not lubricated, multiply *A* by 1.75; for chilled iron bearings, multiply *A* by 2.5.

Factor *F* varies with kind of material (see classification under Conveying Capacities), and within a given classification with the resistance material offers to moving in the trough and past hanger bearings. Values of *F* are:

| Material Class | 1 | 2 | 3 | 4 | 5 |
|---|---|---|---|---|---|
| *F* | 0.4–0.6 | 0.4–0.9 | 0.6–1.2 | 1.4–2.0 | 2.0–5.0 |

For specific values of *F*, see Link-Belt Co. 1933 catalog.

**SCREW CONVEYOR FEEDERS.**—For withdrawing material from a bin at a definite and regular rate a screw has the following advantages over other feeders: 1. Compact, leak proof, dust tight. 2. Relatively cheap in first cost and operation. 3. Can be fitted to bin bottoms of any shape. 4. Acts as a shut-off valve as well as a feeder.

Fig. 2 shows a short feeder of diameter *A* in a closed pipe for the length *D*. The pipe prevents material from flooding out of the bin and acts as a shut-off when screw is idle. Screw is tapered over length *C*, which is attached to the bin, and the trough is flared. Diameter *B* is one size smaller than *A*. The screws are made with heavy steel blades on heavy pipe. Table 1 gives dimensions of the three sizes used for feeders. The carrying capacity for fine material, or material containing not more than 25% of lumps, is about 0.02 cu. ft. per revolution for 9-in.; 0.04 cu. ft. for 12-in.; and 1.1 cu. ft. for 16-in. screws.

For longer feed screws, where an intermediate bearing must be used, sizes are either 9 in. or 12 in. A U-shaped trough is used beyond the length *D*, Fig. 2.

**Table 1.—Dimensions of Screw Conveyor Feeder**

| Size of Conveyor, in. | Max. Size of Lumps, in. | Dimensions, in. (See Fig. 2) | | | |
|---|---|---|---|---|---|
| | | *A* | *B* | *C* | *D* |
| 9XX | 1 1/2 | 9 | 6 | 24 | 24 |
| 12XXX | 2 | 12 | 9 | 36 | 36 |
| 16XXX | 2 1/2 | 16 | 12 | 48 | 48 |

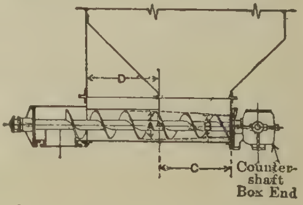

Fig. 2. Screw Conveyor Feeder

It contains the hanger bearing and a screw of full diameter. Clearance between screw and inside of trough should be 3 to 4 in. Length $D + C$ has a screw of a reduced diameter $B$. The rated capacity is the same as for short feed screws, but the lumps may be 50% of total volume.

For cement, pulverized coal and materials which at times flow like fluids, screw feeders are inclined upward at 20 or 30°, with outlet of the trough higher than the intake point. Screws generally have double flights.

**THE THRUST IN SCREW CONVEYORS** should be taken on end castings. These are of various kinds, with ball or roller thrust bearings for heavy loads. Driving ends with bevel gears are general. The Link-Belt Co. places the motor worm gearing and oil-tight gear box on a base plate; gear box is bolted to end of the trough.

**TROUGHS** are well standardized. For cement and similar dusty materials no attempt is made to bolt on a dust tight cover. The cover plate is flanged downward all around and rests in grooves formed by Z-bars on top edge of trough. Dust collecting in the grooves seals cover against further dust emission.

Screw conveyors originally were used for conveying grain but their use has been greatly extended. With properly designed screws, troughs, bearings and drive ends, they handle a wide variety of materials, some of which cannot be conveyed by any other kind of conveyor. For details of screw conveyors and accessories, see catalog of Link-Belt Co., and other makers of conveying machinery.

## PNEUMATIC AND HYDRAULIC CONVEYING

**PNEUMATIC TUBE CONVEYORS** used for transmitting small carriers between departments of shops, newspaper offices, industrial plants, etc., are made by manufacturers [32], [46], [65] (see p. 23–81), and others. The conveyor tube is round or oval, the carriers are short, of a cross-section to fit the tube, and are propelled at 20 or 30 ft. per sec. by vacuum or air pressure. The round tubes are $1\,^1/_4$ in. diam. or larger; the oval tubes are 3 × 6 or 4 × 7 in. Short lengths of small tube, up to 200 ft., can be served by a foot-power pump, but usually a motor-driven blower is used. For a history and description of this system, see *Trans.* A. S. M. E. 1929, MH–51–10.

**PNEUMATIC CONVEYING FOR BULK MATERIAL** was first used in England, developed chiefly in Germany, and now finds extensive use in the U. S. The suction or vacuum system, Fig. 1, comprises an exhauster or pump to produce a partial vacuum, a pipe line through which mingled air and material move, a receiver or cyclone to separate the material from the air, and usually a bag filter to clear the air and keep dust from the exhauster, and prevent it discharging to atmosphere. In a pressure system, the pump delivers air to a pipe line. Material is fed from a supply bin through an air-tight rotary valve into the pipe, moves with the air to a cyclone or separator. The air is discharged to a filter or to atmosphere. The material settles to the bottom of the cyclone.

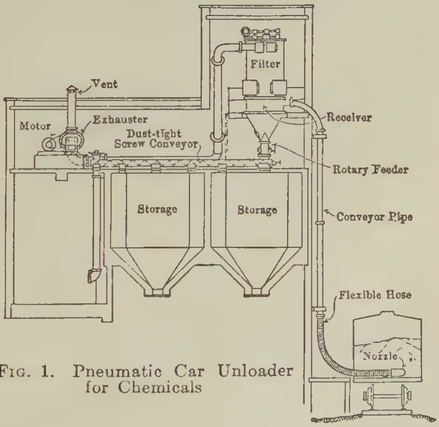

Fig. 1. Pneumatic Car Unloader for Chemicals

**Carrying Capacity** depends on amount of air pumped and difference in air pressure between the two ends of the system. Theoretically, almost any material can be conveyed, but feasibility and cost are determined by practical considerations: 1. Material too large requires large-diameter pipes and a large air pump. 2. Material too dusty may require too large a filter. 3. Material too fragile may be reduced in value by breakage at pipe turns, or dust produced by breakage may require a costly filter. 4. If air pressure is kept low enough to avoid damage to material or to avoid excessive wear at pipe turns, carrying capacity may be too low to be economical.

**The Cost of a Pneumatic System** may be higher than that of a mechanical system. Power cost may be 5 or 10 times as much, but a pneumatic system often is justified by other considerations: *A.* In boats, a flexible suction hose is more easily handled than an elevator leg, takes up less room, cleans up better, requires less shoveling, can work under closed hatches in wet weather. *B.* In unloading railroad box cars, time often is saved, labor costs reduced, delays and demurrage charges avoided. Avoidance of dust sometimes is important. *C.* In handling bulk materials in manufacturing plants, labor often is saved, less dust is produced and less space occupied. Changes in the pipe system to reach new points of intake or discharge are not difficult, and, what often is most important, conditions of safety and health for workmen are better.

A combination of pneumatic handling with mechanical conveying often is desirable. In Fig. 1 material is drawn from the cyclone separator to a distributing screw conveyor. At the New York State Barge Canal terminal in Brooklyn, grain is lifted 80 ft. vertically from barges, and discharged to a distributing belt conveyor.

Fig. 2 shows a Fuller conveyor system on a movable tower for unloading small size soft coal at a cement plant. Coal, at rate of 100 tons per hr., passes through the cyclone separator, is discharged to a short belt conveyor, then dropped on the ground to be distributed later over the storage area by a drag scraper. The tail pulley of the drag line is attached to the rear of the tower and moves with it. See Drag Scraper System, p. 23–16. The boat also carries cement in bulk from the cement plant. At destination, the cement is unloaded by a Fuller-Kinyon pump system on the boat. See below.

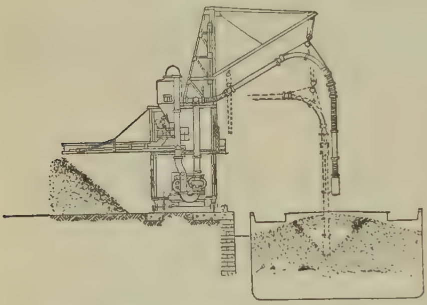

Fig. 2. Fuller Pneumatic Conveying System

Pneumatic systems for conveying bulk material are made by Dust Recovery and Conveying Co., Detroit; Brady Conveyors Corp., Chicago; Federal Pneumatic Systems, Inc., Chicago; Holly Pneumatic Systems, Inc., New York; United Conveyor Corp., Chicago; Fuller Co., Catasauqua, Pa.

**SUCTION SYSTEMS** for collecting and conveying chips and sawdust from wood working machines and dust from grinders are made by B. F. Sturtevant Co., Boston; Allington and Curtis Mfg. Co., Saginaw, Mich.; Kirk and Blum Mfg. Co., Cincinnati, and also by makers of blowers and exhausters. A Kirk and Blum installation in Camden, N. J., handles over 1,000,000 cu. ft. of air per min., collects 150 tons of sawdust daily, and has filters with an area of 200,000 sq. ft. of cloth surface. Similar systems for taking ground coal, rock, etc., from pulverizing mills are made (see p. 23–81) by manufacturers [31], [35], [38], [73], [91], and several makers of grinding mills.

For precautions against fires in blower systems, see publications of National Fire Protection Assoc., Boston. For safety codes for preventing dust explosions, see Bull. 433, U. S. Dept. of Labor, 1927.

**GRAIN UNLOADING.**—Suction apparatus for unloading grain from boats is used at many ports in Europe. The whole system, including power plant and separators, generally is mounted on a barge or float that works on the harbor side of the ship. It transfers grain to river barges while the ship discharges other cargo on the wharf. In the U. S., the largest suction system for unloading grain (1935) is the one in Brooklyn mentioned above; it lifts 6500 bushels per hr. At the public grain elevator, New Orleans, where it was necessary to provide for a 21 ft. range of water level, and for boats differing greatly in width of beam and depth of hold, a pneumatic unloader of 6000 bushels per hr. capacity has been used since 1917.

**THE FULLER-KINYON CONVEYING SYSTEM,** Fig. 3, is not strictly a pneumatic conveyor. At one end of a pipe line a short impeller screw 1 is driven by the motor 2. Material is fed through hopper 3. At discharge end of cylinder in which the screw revolves, compressed air enters through rings 4 and 5. The material when mixed with air acts as a fluid. In the fluent condition it is forced through the pipe line 6 by the displacement of material fed in by the screw and also by the expansion of the compressed air used to create the fluent condition.

Practically any dry pulverized material in quantities up to 300 tons per hr. can be transported by this system over distances of 3000 ft. and elevations of 150 ft. or more. The system is widely used in cement mills, and for other pulverized materials as lime, soda ash, starch, kaolin, bauxite, etc. The pipe line may range from 2 to 8 in. diam. according to amount of material. Branch pipes are connected to the main line by 2- or 3-way valves, usually operated by hand, but sometimes by automatic and remote control.

Bins can be filled in desired sequence; the system will continue to work automatically so long as any bin has room to receive material. Deliveries under automatic control have been made to 48 bins in one system. To mix and blend raw materials in cement making, the discharge from several pipe systems may be controlled automatically according to predetermined time intervals. Hot materials up to 1000° F. are successfully conveyed. Pipe lines may be water jacketed for cooling cement in process of manufacture. Steam jacketed lines also are in use.

Fig. 4 shows a Fuller-Kinyon portable pump, used chiefly on construction jobs to unload bulk cement from box cars or barges, to convey it to mixer bins or storage, and to reclaim it from storage to the bins. The pump is a motor-driven self-contained unit. Clutches control the power drive to the traction wheels. Cement is discharged through flexible hose which may be connected to any of the steel pipes leading to delivery point.

Several boats on the Great Lakes are equipped with the L. D. Smith system of drag scrapers (see p. 23–17) and a Fuller-Kinyon pump. Cement is pumped ashore at rate of 1400 barrels per hr. through a flexible hose to the pipe lines which distribute cement to silos or pack houses.

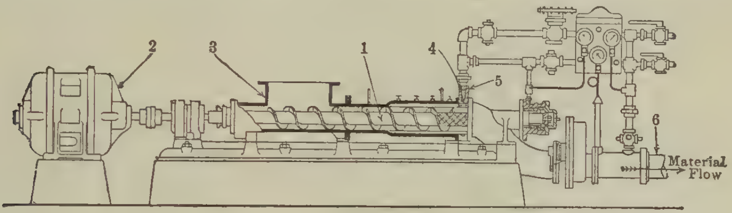

Fig. 3. Fuller-Kinyon Pump

The Fuller-Kinyon system often is cheaper and more convenient than any combination of mechanical elevators and conveyors. For short distances power consumption may be more, but for average or long distances it is apt to be less. Its advantages are: Pipe can be run anywhere over, under or around obstacles; material conveyed is always enclosed and risk of fire, explosion, or injury to workmen is low. For temporary jobs of road making or building construction, its erection, dismantling and moving are relatively cheap.

**TRANSFER OF MATERIALS UNDER DIRECT PRESSURE.**—The Fluxo pump (F. L. Smidth & Co., New York) is used in some cement plants to transfer cement or dry pulverized raw materials to and from storage bins. A carriage runs on a track at one side of a row of silos or storage bins, and connects with a pipe in the base of the silo by a flexible hose. On the carriage are two tanks, a vacuum pump with an air filter, an air compressor and an electro-pneumatic control apparatus. When the current is being drawn into one tank by suction, it is being expelled from the other by air pressure. The operation is reversed by the control apparatus, the tanks alternately filling and emptying. The flow, from silo to transport line to which the machine is connected, is continuous.

The Kennedy transport system (Kennedy-Van Saun Engg. Corp., New York) consists of a single tank, to which cement, or other pulverized materials flow, suitable valves, air under pressure and a transport pipe line. At a predetermined weight of material in the tank, springs on which the tank rests deflect, the supply is shut off, the bottom valve opens, and air admitted to top of the tank forces the material out through the pipe line. The cycle automatically repeats.

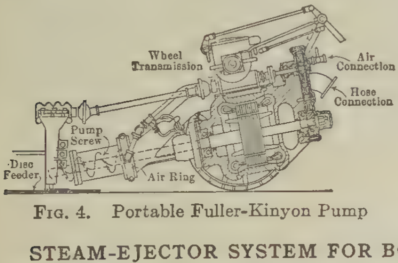

Fig. 4. Portable Fuller-Kinyon Pump

**STEAM-EJECTOR SYSTEM FOR BOILER HOUSE ASHES.**—The Steamatic ash conveyor system (United Conveyor Corp., Chicago) has in many cases replaced the steam-jet system of handling ashes. In the Steamatic system, air flow is produced by a ring-nozzle ejector and a Venturi tube placed at the discharge end. The following claims are made: 1. Low steam consumption. 2. Relatively little wear on pipe lines and pipe turns. 3. Since ashes are in contact with steam for only 3 ft. of travel, they enter the bin dry, and do not pack, or freeze in winter. 4. Less noise. 5. No danger of explosion in storage bin. This system requires steam at 70 lb. per sq. in. or higher, will carry up to 200 tons of ashes per day up to 300 ft. distance and lift through 100 ft. Pipes are

4, 5, 6, 8 in. diam. The 8-in. size handles large clinkers and is most economical of steam per ton of ashes carried. Small pipes may be used as branch lines for fly ash and soot.

The Nuveyor system (United Conveyor Corp.) is similar in principle to the Steamatic. The pipe line is the same, but to produce suction a positive air exhauster of the Roots blower type or a multi-jet exhauster is used. In both cases ashes pass to a cyclone separator; then by an automatic timing device, which acts every 90 sec., a release valve opens, suction stops for 5 sec. and ashes in the cyclone drop into the storage bin. Fig. 5 shows such a system with an air washer between cyclone and exhauster. No dust enters the latter and discharge to atmosphere is clean. The air washer acts also as a silencer. The Nuveyor will handle 30 tons of ashes per hour, is quiet in operation and ashes entering the storage bin are dry. The system is operated by remote-control buttons at points where ashes are fed to pipe line.

**ASH DISPOSAL BY WATER FLOW.**—In the Hydrojet system (Allen-Sherman-Hoff Co., Philadelphia) ashes accumulated under boiler furnaces are dislodged by a water jet at 100 lb. per sq. in., and moved through a trench below the basement floor by similar jets. Fig. 6 shows the system applied to the ash pit of a chain grate stoker. The whole apparatus is enclosed. The jet breaks down the pile of ashes; the mixture of water and ashes flows into the trench under the floor, lined with U-shaped cast-iron plates; nozzles at intervals deliver jets in the direction of flow. Outside the boiler house the discharge can flow to waste land or to a sump from which ashes are removed by grab bucket or pumped to a drainage bin for removal by car or truck. Advantages claimed for this system are: 1. No escape of dust, gas or steam into basement. 2. Men cannot be gassed or burned. 3. No leakage of air from basement into furnace to disturb combustion. 4. Operation is intermittent; time is available for repairs when necessary. 5. Overhead ash hoppers and cars are not used; boiler house can be built 10 ft. lower.

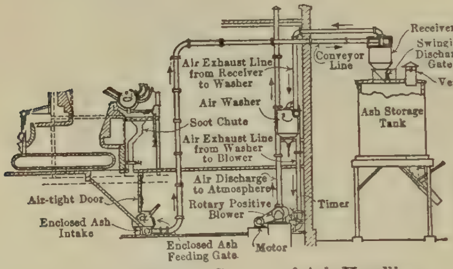

Fig. 5. Nuveyor System of Ash Handling

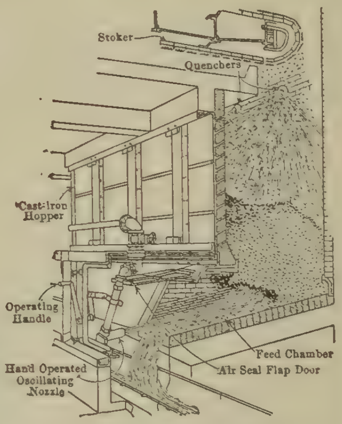

Fig. 6. Hydrojet System of Ash Removal

The Hydrovac dust handling system (Allen-Sherman-Hoff Co.) for boiler houses removes siftings under stokers, fly dust from boiler settings, soot and floor sweepings, by means of air flow under vacuum produced by high pressure water jets in a Venturi tube. The siftings can be blown into a furnace, refuse can be collected in a tank for removal or discharged into the water trench of the Hydrojet system.

For mechanical methods of ashes handling, see p. 23–57. For hydraulic ash handling systems see *Trans.* A.S.M.E. 1928, MH–50–12.

# PACKAGE HANDLING

**TYPES OF PACKAGE ELEVATORS.**—1. For boxes, barrels, bales and sacks, the rigid arm elevator, Fig. 1, will discharge over head wheel only. 2. The automatic arm elevator, Fig. 2, has carriers arranged to lift and lower; lifting side is so hinged that it will dump a barrel or sack forward when a lever on the arm contacts with an adjustable cam on the lifting side of elevator. On lowering side, the arm is rigid. Packages going down are deposited on skids at unloading point. 3. Suspended tray elevators, Fig. 3, have trays so hung on pivots between two chains that center of gravity of loaded tray is well below points of suspension. These trays, when made with finger bottoms, will pick up packages from skids on the up run and deposit them on skids on the down run. Solid bottom trays require loads to be put on or taken off by hand. Suspended tray elevators run at not over 30 ft. per min. 4. Elevators with corner-hung trays, Fig. 4, are similar to [3] but the chains are not directly opposite each other and pivots are not in line. This makes tray more stable in passing around turns and on straight runs, but wheels are out of line and the drive is not so simple. 5. Tray elevators with selective discharge: Style A, long trays with fingered bottoms with one loading compartment for each discharge point. Receiving fingers at each floor are set to register with compartment for that floor. Style B, fingered trays dumping forward on up run. Tray guides have a throw switch at each floor to tilt the tray. Switches are controlled by latches on tray which are set by an indicator at loading point.

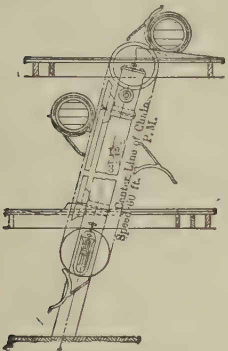

Fig. 1. Rigid Arm Elevator

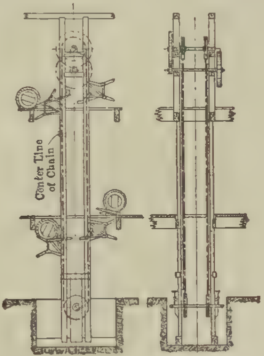

Fig. 2. Automatic Elevator

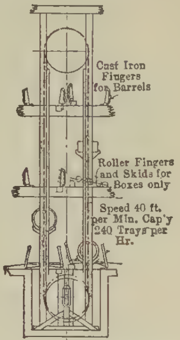

Cast Iron Fingers for Barrels
Roller Fingers and Skids for Boxes only
Speed 40 ft. per Min. Cap'y 240 Trays per Hr.
Fig. 3. Suspended Tray Elevator

Package elevators in these various styles are made by nearly all builders of conveying machinery. Much ingenuity has been spent on special forms. Elevators for trays of dishes, elevators to deliver to or to take from roller conveyors, elevators for selective discharge are made (see p. 23–81) by manufacturers [46], [51], [55], [65], and others.

**PACKAGE CONVEYORS.**—1. Packages of uniform size, not too heavy, can be moved in a trough by pushers attached to a

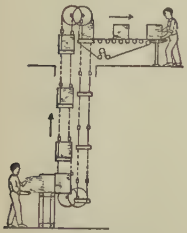

Fig. 4. Corner Hung Tray Elevator

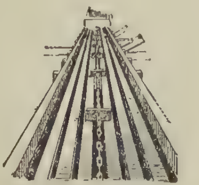

Fig. 5. Single Chain Package Conveyor

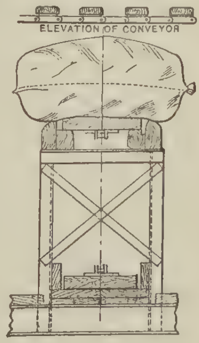

Fig. 6. Slat Conveyor

single chain. See Fig. 5. 2. Packages can be carried on slats which slide on both runs, Fig. 6. 3. Slat conveyors on roller chains will handle packages of any size or weight. Discharge is generally over the end, but movable plows, Fig. 7, will deflect boxes sideways for intermediate discharge. 4. Belt conveyors are used in shops, assembly departments, stores, post-offices, etc., for handling stacks of light package goods of all kinds. For this work the conveyor has straight tubular idlers and the edges of the belt are supported to prevent sagging between idlers. Fig. 8-A shows the construction with steel guards used in department stores, the goods being delivered by chute from above. Fig. 8-B shows the construction where packages are tossed on the belt from below. For light work the belt may slide on a hard wood plank. 5. Packages of uniform size can be carried long distances and at any angle of slope by wheeled carriages attached to a single chain, Fig. 9. 6. Inclined conveyors, Fig. 10, are used for handling and piling bags and bales. They have a belt to which cleats are attached, or else push-bars mounted on two strands of chain.

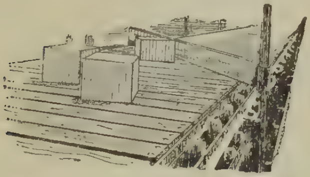

Fig. 7. Slat Conveyor on Roller Chain

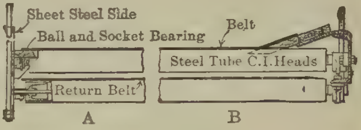

Fig. 8. Belt Conveyor for Packages

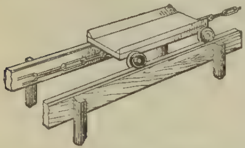

Fig. 9. Package Carrier

Package conveyors are built by all makers of conveying machinery. For information concerning them and special conveyors to work with gravity roller systems, see catalogs of the several makers. Selective discharge from belt or roller conveyors is described by W. O. Hildreth, *Trans.* A.S.M.E, MH–51–8, 1929. For selective discharge actuated by photo-electric relay, see *Matl. Handling and Distrib.*, May 1931, and other issues in 1931 and 1932. The electrical apparatus is made by General Electric Co.

A novel form of portable flexible conveyor for goods in bales and sacks is the Twinveyor (Clark Tructractor Co., Battle Creek, Mich.). It comprises several 8-ft. sections coupled end to end by flexible joints. Each section is made of two parallel tubes 4 in. diam. geared together and driven by a 5-Hp. motor, with a blunt screw thread on the outside. As the screws revolve the bag or bale resting on them acts as a nut and travels at 90 ft. per min. The original installation is described by J. T. Buzzo, *Trans.* A.S.M.E., MH–50–2, 1928.

**THE MONORAIL CHAIN CONVEYOR** consists of a power-driven chain suspended from trolleys on a continuous track, usually overhead. The chain joint pins are in a vertical plane. It bends around sprocket wheels or nests of rollers, or it can bend around tracks curved in a vertical plane if the proper chain is used. Loads are carried on hooks, racks, trays, slings, etc., hung from the trolleys. Speed generally is less than 75 ft. per min. The chain may be in one plane or several. It may serve several floors of one building or connect several buildings. Work can be done on suspended pieces as they travel along to dipping vats, baking ovens, etc. Monorail chain conveyors do work for which floor trucks and freight elevators otherwise would be required. They occupy no floor space, require little power and provide a steady movement of parts from one operation to another and to final assembly, inspection and shipment.

Fig. 10. Inclined Conveyor for Piling Packages

Fig. 11 shows a light trolley with 3 1/4-in. pressed steel ball-bearing wheels with two styles of hangers. The hangers are forgings which pass through the middle of a rivetless drop-forged chain. The pins in this chain have double heads and there is clearance enough in the joints to allow side flexure. These trolleys also are made with 4 wheels.

Fig. 12 shows a heavy trolley with 5-in. chilled roller-bearing wheels, running on a double angle track. The forged hanger occupies one pitch of a steel roller chain, and has a transverse joint to permit chain to roll around curves in a vertical plane without side strain on chain pins. Trolleys and hangers of this type (Palmer-Bee Co.) will carry loads up to 3000 lb.

**Calculation of Monorail Chain Conveyor.**—(Adapted from Link-Belt Data Book). 1. Make a layout, and scale off amount of chain required. 2. Assume a chain speed and a spacing of loads, as determined by time required to travel a certain distance, or the number of pieces to be delivered per min. 3. Sketch tray or carrier and make the horizontal and vertical turn so that carriers clear each other even if they swing. See Fig. 13. 4. From catalogs of makers select a trolley suitable for the load. These have been standardized. 5. As a first approximation, assume horsepower pull for a single-plane conveyor to be 5% of total moving weight (chains, trolleys, carriers, loads), about 7% for a conveyor with a few easy vertical curves, and 10% for one with many curves. 6. Select a chain strong enough for (5), and suited to the trolley. 7. Locate drive where sprocket wheel has at least 90° arc of contact with chain; 180° is better. The take-up should be where chain is under light load. Vertical turns work best if chain passing them is not under heavy tension. 8. For more accurate determination of chain tension and horse-power, calculate chain pull for each run and each turn. Thus, $C_H = WLX$; $C_C = YC$, where $W$ = weight of moving parts, lb. per ft., empty or loaded as the case may be; $L$ = length of run, ft.; $X$ = 0.03 for ball- or roller-bearing trolleys; = 0.05 for bronze-bushed trolleys; $C_H$ = pull for each straight horizontal run, lb.; $C_C$ = pull for each corner, take-up idler or roller turn in horizontal plane, lb.; $C$ = chain pull at turn, lb.; $Y$ = 0.03 for sprocket wheel or roller turn; = 0.02 for a traction wheel turn. The pull for a double curve in passing from one level to another is

$$C_V = WSX + CZ + HW,$$

where $W$ and $X$ are as above; $S$ = horizontal length of double curve, ft.; $H$ = height of double curve, ft., taken as (+) when travel is up, (−) when travel is down; $C$ = chain pull at entrance to the curve, lb.; $Z$ = friction factor due to radial pressure of trolley on curve; for ball or roller bearings $Z$ = 0.001 per deg. of inclination from the horizontal of tangent between curves; for bronze-bushed trolley wheels, $Z$ = 0.002. 9. To algebraic sum $C_H + C_C + C_V$, add 3% for friction at drive wheel. Check this against strength of chain, assumed in (6). 10. The radial pressure on each trolley is $P = BC/R$, where $B$ = trolley spacing, in.; $R$ = radius, in., to center of chain on curve; $C$ = maximum chain pull at any curve, lb. Check this with permissible trolley load. If too great, space trolleys closer or make radius longer. The longer the radius the better will be the operating results.

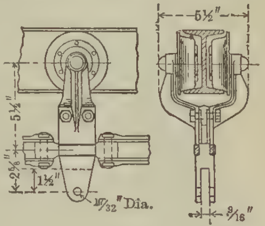

Fig. 11. Monorail Conveyor

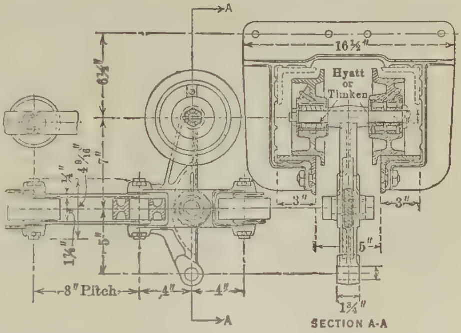

Fig. 12. Palmer-Bee Overhead Conveyor

Where conditions make it difficult or impossible to drive a chain by a sprocket wheel, an auxiliary drive acting on the straight run of chain may be used. The auxiliary chain is short and has pushers which engage links of the conveyor chain. The Webb system of using a number of these devices synchronized, and with automatic speed control, is described by H. C. Rundle, *Trans.* A.S.M.E, MH–53–7, 1931.

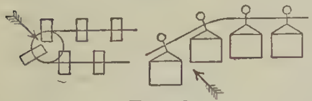

Fig. 13

Monorail chain conveyors are made (see p. 23–81) by manufacturers [50], [57], [69], [88], and other makers of conveying machinery.

**ROLLER CONVEYORS,** Fig. 14, will convey down slopes of 1 1/2% to 5%, boxes, packages, cans, bottles, lumber, steel products, almost anything that has a smooth face or side. The goods travel over rollers of steel tubing fitted with ball bearings. Capacities range from a few pounds up to 4 tons per roller. Some conveyors have spaced wheels instead of rollers. Rollers are assembled in straight sections, curves, switches, $Y$-assemblies and roller spirals. They can be set on floors supported from walls or hung from ceilings. Roller conveyors have been highly developed and have a wide field of usefulness. For detailed information, see catalogs and bulletins of manufacturers [46], [51], [55], [65], [83]. (See p. 23–81.) For a description of an elaborate system of Logan Co. conveyors with a new form of switch, see C. K. Pevear, *Trans.* A.S.M.E., MH–52–6, 1930.

**SPIRAL CHUTES** are made by manufacturers of roller conveyors, and by Hazlett Spiral Chute Co., Oaks, Pa. Some are made with roller beds, others have steel plate bottoms. They carry boxes, packages and even some kinds of unwrapped goods from upper to lower floors. Some are made with two or more spirals. They provide means for delivering different classes of goods to separate unloading stations at the lowest floor of a building, or goods can be passed from one floor to another on one spiral without interfering with goods on other spirals. Fig. 15 shows diagrammatically a chute with 6 spirals serving 13 floors of a clothing factory. The letters *A*, *B*, *C*, *D*, *E*, *F*, indicate separate spirals and the arrows show inlets and outlets. *G*, *H* and *J* are straight chutes in the system, not part of the spiral chutes, but all combine to provide a gravity flow for raw materials from the 13th and 11th floors to manufacturing floors below, and finally as finished goods to the shipping room in the basement.

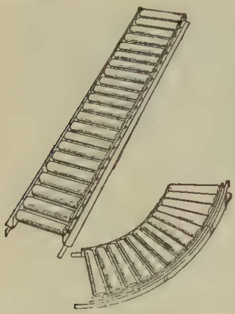

Fig. 14. Roller Conveyor

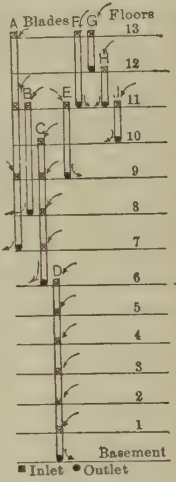

Fig. 15. Scheme of Spiral Conveyor System

**PROCESSING OVENS.**—Monorail and other forms of chain conveyors are used to carry cores, lithograph plates, and enameled metal parts through drying and baking ovens, and to carry metal parts through ovens in which they are dipped and drained. Such ovens are made by Young Bros. Co., Detroit; Foundry Equipment Co., Cleveland. Other forms of processing ovens are equipped with roller beds for handling cores and other parts on pallets. Some carry the work on trays suspended from two chains.

The conveyor tunnel kiln made by Swindell-Dressler Co., Pittsburgh, conveys tile, refractory brick, and similar ceramic materials through a firing kiln by means of rocking frames which support the materials. In other forms of the Dressler kiln, castings, steel plate or other heavy materials are annealed while they move through the kiln on a train of cars propelled by a ram.

# VEHICLES

## 1. TIERING MACHINES, LIFT TRUCKS AND SKIDS

**TIERING MACHINES, Portable Elevators, Stackers** for piling cased goods, barrels, bales, rolls of paper, etc., are made in a variety of styles and sizes by manufacturers [10], [25], [48], [74], (see p. 23–81) and others. For light service or occasional use they are operated by hand-crank, fitted with a safety brake to prevent it from flying back and injuring operator. For regular service, an electrically-driven machine is more useful. These machines also are used to handle dies to the level of press-beds, put up and take down overhead motors and shafting, support rigging and platforms for painting, cleaning and repair work, etc. Fig. 1 shows a hand-power stacker for lifts of 4 to 12 ft. The frame is hinged so that the machine can pass through a doorway. Similar hand-power and electric machines with telescopic frames are made for 2000 lb. loads and 12 ft. lifts.

The Revolvator (Revolvator Co.) has a turn-table base which locks in any of 4 positions. It is easy to load and convenient to use in narrow aisles or to stack goods against a wall. Revolvators, hand-driven or electric, will lift 5000 lb. loads to heights of 18 ft. See Fig. 2. They travel on 4 wide-face roller-bearing wheels, but when they are used for stacking, the load is transferred from wheels to legs so that the frame cannot roll.

**SKIDS AND LIFT TRUCKS.**—The following is taken from Simplified Practice Recommendation R95–30, U. S. Dept. of Commerce, 1931: The skid platform, or skid, is a flat, rectangular platform mounted usually on two parallel runners at or near the sides, or four legs near corners of platform. It is handled by a lift truck comprising two parallel, horizontal frames, on 3, 4 or 6 wheels. The upper frame, or platform, is so mounted that it may be raised above its lowest position. The truck, with lifting platform in the lowest position, is run under the skid; the lifting platform is raised, lifting skid supports clear of the floor. The truck then may be moved, carrying the skid. When skid is to be set down, the lifting platform is lowered until the skid supports rest on the floor. With lifting platform in its lowest position, the lift truck may be withdrawn.

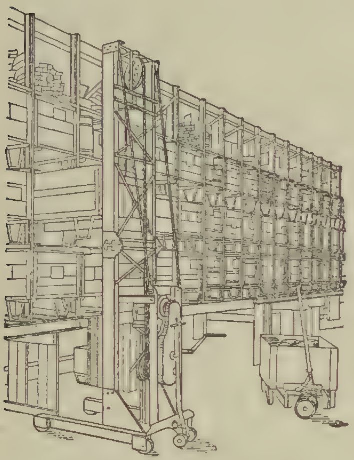

Fig. 1. Hand Power Stacker

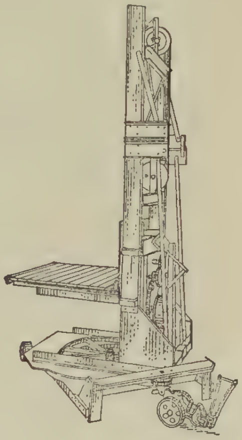

Fig. 2. Revolvator

Various attachments to skids have been developed to carry different commodities, including sides and ends permanently fastened to skid, superimposed removable boxes, fixed shelves and racks, removable vertical posts at sides or ends, and special attachments for particular commodities. Plain skid platforms carry paper, hides, rubber, machinery, sacked goods, boxed, crated and barreled goods and numerous other materials.

Advantages of handling goods on skid platforms include savings in time and labor, avoidance of loss or damage from piecemeal handling, and facility in handling and storing in large units without breaking bulk. Indirect advantages are simplified cost and inventory accounting and greater mobility of stores, supplies and materials. The paper and other industries began the shipping of goods on skids. Advantages of " skid shipment," include all advantages of intraplant skid handling, plus savings in packing material, labor, cost of loading and unloading, and elimination of breaking bulk in rehandling. Savings actually made range from 25 to 90%.

**Clearance and Overall Dimensions.**—To standardize dimensions of skid platforms to allow them to be used interchangeably in different plants and by all makes of lift trucks, a committee of manufacturers and users of skids and trucks, working with the U. S. Dept. of Commerce, adopted (1931) the following: Clear height under bottom of platform, either 8 or 12 in.; least width between legs or runners, 29 in. Overall dimensions: No. 1, 54 in. long, width not over 33 nor under 32 in.; No. 2, 60 in. long, 42 in. wide.

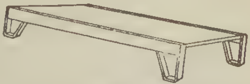

Fig. 3. Steel Frame Skid

**Skid Construction.**—To withstand rough handling, skid platforms should be strongly built. Fig. 3 shows one style (Lewis-Shepard Co.). The frame is arc-welded steel; the top is wood; the open sides allow a lift truck to be pushed in from any of the 4 sides. Other skids are: Built-in roller-beds (Yale & Towne); all-steel platforms of one steel plate bent to form top and sides (Truscon Steel Co., Cleveland); mounted-on dump-hoppers (Wilder-Strong, Monroe, Mich.). Skids which do not require a lift truck are made by manufacturers [22], [50] (see p. 23–81). They have 2 wheels in back and legs in front. A separable handle, fitted with a wheel, is thrust under the platform and engages a pin; when the handle is pushed down the front of the platform is lifted, the weight is taken off the legs and the platform is on rollers. Boxes, on skid legs or runners, in which small parts are handled and stored, as in Fig. 1, are made by the companies named above.

**LIFT TRUCKS.**—Lift trucks in 3 or 4 styles are made to handle loads from the lightest up to 5 tons. For the heaviest service, some trucks have a hydraulic lift operated by the pull-handle, which raises skid platform to clear the floor 3 in. or more. See Fig. 4. The "Jacklift" truck, Fig. 5, has a step-by-step ratchet lift; it is made in several models with lifts from 2 1/2 to 6 in. for loads up to 5 tons. The "foot-lift" model is worked by a treadle. Similar lift trucks are made by manufacturers [10], [48], [74], [95] (see p. 23–81), and others. They differ chiefly in lift and release mechanisms. All makers will furnish trucks with long frames for handling long narrow articles, core racks, drying frames, etc. Trucks with flanged rollers to run on tracks also are listed.

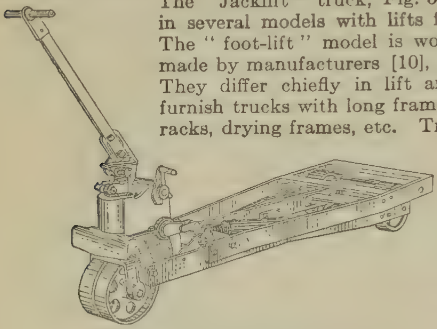

Fig. 4. Hydraulic Lift Truck

*Trans.* A.S.M.E., MH–50–4, 1928, MH–51–9, 1929, contain papers on handling materials on skids. These papers and the discussion of them bring out the following advantages of the system: 1. Easier handling. 2. Lower costs. 3. Time saved. 4. Less material carried in stock and inventory. 5. Greater safety to men. 6. Saving in packing for shipment. 7. Lower freight charges.

Storage systems using steel racks, to which box-skids or platform-skids are brought by lift trucks, and stored by a stacker are made by manufacturers [10], [48] (see p. 23-81), and others. Fig. 1 shows the parts of such a system. Material can be stored ceiling-high, floor space is saved and all skids easily can be reached and removed.

## 2. ELECTRIC TRUCKS AND TRACTORS

**ELECTRIC TRUCKS, TRACTORS AND TIERING MACHINES.**—Bulletins of the following companies (see p. 23–81) show these machines and describe the uses to which they are put: [5], [6], [7], [27], [58], [95]. Developments have been the use of stronger steel frames, roller and ball bearings, better motors, enclosed gearing, better lubrication, large capacities, and adaptation to handling a greater variety of products. Many forms of tractors, lift-trucks, tiering machines and crane-trucks are in use. See *Trans.* A.S.M.E., MH–53–4, 1931. Various types are in use as follows:

1. **Trucks with Fixed Platforms** used in shops and warehouses to carry loads up to 6000 lb., and also in railroad service to handle baggage. The operator stands on a hinged platform at one end, one hand on the steering-lever, the other on the controller handle, his foot on the brake pedal. If he steps off, the brake is set and the current shut off. Fig. 6 shows a small truck. These travel 4 or 5 mi. per hr. loaded, steer on all four wheels, are reversible and can be handled in small spaces and narrow aisles. Trucks with good springs and 20-in. wheels can run over rough floors and block pavement.

2. **Trucks with Lift Platforms,** used principally to handle material on skid platforms (see p. 23–74), are built to lift and carry loads from 4000 to 20,000 lb. In low-lift trucks a cam or link motion in the base frame raises the platform to give floor clearance. On high-lift trucks the platform is raised by cables or chains, by a screw working in a movable nut, or by hydraulic cylinders. All truck builders furnish machines to handle standard skids (see p. 23–75) as well as special or higher skids. Wheels under platforms of lift-trucks for low skids seldom are over 10 1/2 in. diam. and roughness and unevenness of floor affect them more than trucks with larger front wheels. For effect of bad floors, see p. 23–78.

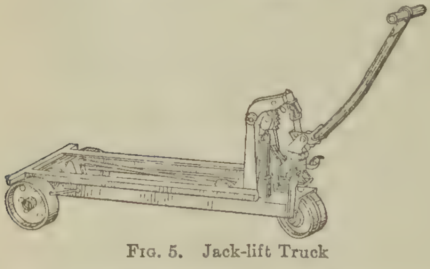

Fig. 5. Jack-lift Truck

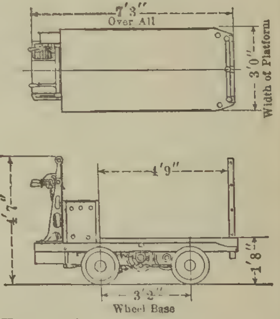

Fig. 6. Electric Platform Truck

Fig. 7 shows a 4000-lb. low-lift truck which will lift 4 inches, skids 8 in. high. Fig. 8 shows a high-lift truck which will raise a 6000 lb. load 6 ft. The platform is 55 × 27 in. High-lift trucks pile and tier goods, serve presses and handle freight to and from box cars. Trucks of this type are made with special platforms or attachments to do such work as the following: *a.* Pick up bales from floor by thrusting forks under them (called *chiseling*). *b.* Handle 5-ton reels of wire by pulling them from floor to a tilting platform by a power winch. *c.* Carry piles of tin-plate with a top clamp to keep pile from shifting. *d.* Place heavy stamping dies in position on a press platen.

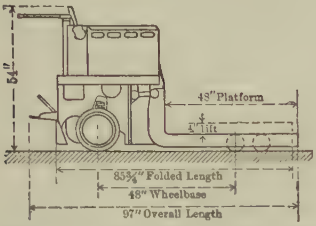

Fig. 7. 2-Ton Electric Lift Truck

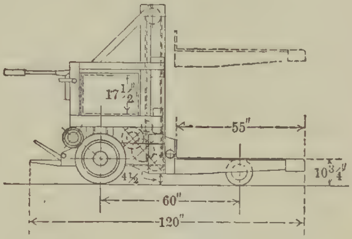

Fig. 8. 3-Ton Electric High-lift Truck

**THE FORK TYPE LIFT TRUCK.**—The forks, Fig. 9, can be lowered to the floor to pick up material resting on battens, or even chisel under some kinds of packages on the floor. Machines of this type are compact enough to work in and out of box cars, will handle loads of 1/2 to 3 tons or more.

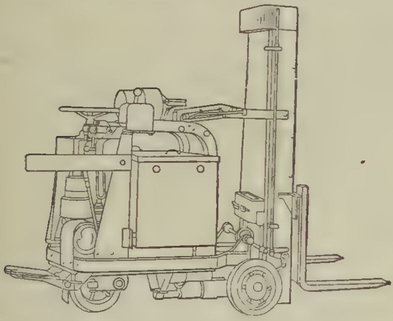

Fig. 9. Fork Type Lift Truck

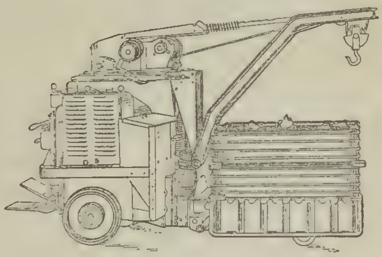

Fig. 10. Electric Lift Truck with Crane

When fitted with telescoping uprights they will lift and tier to heights of 6 ft. A truck which acts as a tractor, lift-truck, crane-truck, and portable crane is listed in four sizes; crane capacity up to 2000 lb.; platform capacity up to 10,000 lb. See Fig. 10.

Storage battery cranes for shop service are made by manufacturers [7], [27] (see p. 23–81), and others. They have low bases fitted with booms, fixed or telescopic, rotating and with luffing motion. Capacities are up to 6000 lb. at 7 ft. radius, but with wheel base short enough to permit maneuvring in shop aisles.

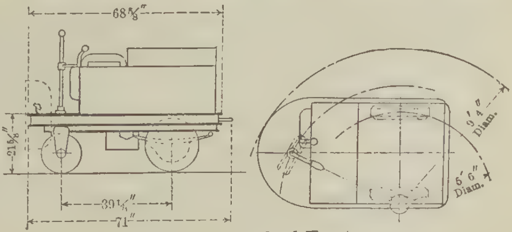

Fig. 11. 3-Wheel Tractor

**ELECTRIC TRACTORS** are built in various sizes with various kinds of storage batteries by makers mentioned above. The smallest tractors, Fig. 11, have three wheels, two for drive, one for steer. Intermediate sizes steer on two wheels; the largest and most powerful on all four wheels. Some makers list tractors with 4-wheel drive. Some tractors have flanged wheels to run on narrow-gage tracks.

Tractors are economical where quantity of material handled is enough to warrant use of trains of trailers, and where movement of trains can be arranged according to a timetable. In a railroad shop in Milwaukee, covering 3 sq. mi., the stores department and various shops are served by trains of trailers drawn by storage battery tractors. They make the circuit every 45 min. and stop at 11 stations en route. Where possible, material is kept on skids, handled, moved and delivered to trailers by lift-trucks. Empties are placed at the various stations as required, to be removed by a later train when loaded. Many railroad stations use several tractors, with 50 to 100 trailers per tractor. Advantages of this system, as compared with 2-wheel hand-pushed trucks, are: 1. 50% or more time saved in getting freight from wagon or truck to freight car, or *vice versa*. 2. More systematic loading of freight cars and more prompt dispatching. 3. Less damage to freight, fewer complaints from shippers. 4. Saving in cost of freight handling sufficient to pay for entire investment in a few years; in some cases in a few months.

Trucks and trailers are made by many manufacturers; some (see p. 23–81) who specialize in trailers for haulage by electric or gasoline powered tractors are [5], [19], [24], [58], [62], [84], [95].

**Table 1.—Cars and Trailers for Different Services**

(Easton Car & Construction Co., Easton, Pa.)

| Moved by | Conditions and Loads | Style of Car (see note) Choice 1st | 2d | 3d |
|---|---|---|---|---|
| Power | Accurate trailing | A | B | C |
| " | Accurate trailing and reverse | A | D | ...... |
| " | Good or rough runways, heavy loads on 2 or 3 trailers | C | A | D |
| " | Good runways, heavy loads on 4 or more trailers | B | A | C |
| " | Rough runways or dirt floors, heavy loads on 4 or more trailers | C | A | ...... |
| " | Rough runways or dirt floors, light loads | A | C | ...... |
| " | In conjunction with considerable hand trucking | B | C | D |
| Hand | Good runways, light loads | B | D | C |
| " | Poor runways, dirt floors, heavy loads | C | ...... | ...... |

Note.—A—4-wheel-steer trailer; B—Caster trailer or truck; C—Fifth-wheel trailer or truck (Wagon-type); D—Balanced trailer or truck. On right-angle turns in 7 ft. aisles, caster trailers will creep outward 3 or 4 in.; fifth-wheel, 7 to 10 in.; balanced trailers with cross-chain connections. 7 to 10 in.; 4-wheel steer trailers will not creep. The larger the radius of turn, the less the creep.

**Four-wheel Steer Trailers** guide well but do not turn sharp corners readily and are awkward to move by hand.

**Caster Trailers** carry most of the load on two large wheels and steer by swivel casters at front or rear. They move easily, steer well and can be maneuvred in narrow aisles. They are the best for general use.

**Fifth-wheel or Wagon-type Trailers** or trucks are for heavy loads and rough service. They are not reversible. They can be made with large wheels for use on bad paving or rough floors.

**Balanced Trailers** or trucks are like warehouse hand trucks, carry the load on two large wheels under middle of the body and have single or double casters at the ends. They turn easily but do not guide well at high speed.

On smooth new floors, trucks and trailers with steel wheels start easier and roll easier than rubber-tired wheels, but on most floors and on all runways, ramps and paved yards the rubber-tired or canvas-cushion tired wheels have the advantage. The pull is less, goods are not shaken or damaged, wear and tear on the truck is less, noise is less and damage to floors is eliminated.

CONDITION OF FLOORS AND RUNWAYS.—Table 2, based on tests of trailers fitted with roller bearings and solid rubber tires shows that power required to keep them

**Table 2.—Rolling Resistance of Trailers on Various Floors and Roads**

(Plain Bearings)

| Kind of Surface | Average Rolling Resistance, lb. per ton |
|---|---|
| Hard plank; wood block; concrete; asphalt in good condition | 20 |
| " " " " but worn | 40 |
| Macadam in good condition; gravel rolled hard | 35 |
| " poor condition | 70 |
| Dry earth, hard, dusty | 60 |
| Ordinary earth road | 100 |
| Muddy earth road; frozen ruts; loose gravel; loose sand | 200 |
| For each 1% of up-grade, add 20 lb. per ton. | |

moving varies greatly. Incidental disadvantages of poor floors and runways are: 1. Tractor operator will run slowly to prevent goods being jolted off trailers. 2. Cost of repair and maintenance of equipment is increased. 3. Labor cost due to delay and stoppages is increased. Checkered steel plate or hard wood plank laid lengthwise to form runways or ramps often will prove profitable. On rough floors, the advantage of ball or roller bearings tends to disappear, especially at speeds above 3 mi. per hr. On good floors the rolling resistance of 8-in. wheels fitted with roller bearings is four times that of 20-in. wheels. See Hellmich, in *Zeit.* V.D.I., Mar. 4, 1933.

**COST OF HANDLING BY ELECTRIC TRUCKS.**—C. B. Crockett and H. J. Payne (*Trans.* A.S.M.E., MH–50–3, 1928), give the following as average costs per year: Depreciation of electric truck, $300; depreciation of storage battery, $200; depreciation of charging equipment, $15; interest, maintenance and storage charges, $245; electric current for charging batteries, $225; maintenance and repairs, $225; total, $1210. This sum is approximately equal to a man's wages. To it add wages of operator, and total cost of operating an electric truck is, roughly, two men's wages. If an electric truck can save the labor of only two men, its direct saving is doubtful; if it eliminates 3 or more men, it can show a profit. Labor cost alone is not all that should be considered. If trucks speed up handling, reduce lost time and delays, and increase output of a plant, cost of truck equipment must be balanced against cost of increased plant necessary for increased production. Material kept moving reduces inventory, material in process and money tied up thereby. These differences should be credited to the truck system.

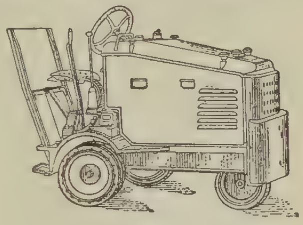

FIG. 12. Gasoline Tractor

The Crockett-Payne diagrams (see above) show: 1. Trucking by hand may be cheaper than haulage by truck if the work takes only $^1/_7$ of full time, *i.e.*, 1 $^1/_5$ hrs. per day, or 44 full days per year. 2. Fixed charges of electric trucks may be higher than those of gasoline trucks, but under favorable conditions cost of power and repairs is less. 3. For long hauls, or 24-hr. service, cost of handling by gasoline truck may be less than that for haulage by storage battery truck. 4. For bad floors or badly paved yards, haulage by gasoline truck may be cheapest. Electric haulage is particularly suited to transfer of material of considerable volume and weight between departments of shops and warehouses, where haulage can be done on a regular schedule that allows 5 to 7 hr. for recharging batteries; where floors inside or paving outside are fairly good; where quiet operation is an advantage and where fire risk and noise of gasoline tractors may be objectionable.

**GASOLINE TRACTOR TRUCKS AND TIERING MACHINES.**—For general haulage and service in shops, warehouses and freight houses, gasoline tractor trucks are made in sizes corresponding closely to storage battery trucks. Clark Tructractor Co. makes tractors in various sizes. The smallest, Fig. 12, weighs 2700 lb., has a draw-bar pull of 2000 lb., and can haul 25 tons on trailers over good floors. It is 39 in. wide, 78 in. long, 59 in. high, has a 2-wheel drive, 1-wheel steer and will turn on a radius of 51 in. Another model for travel over very rough floors or paving has four wheels, and a turning radius of 92 in. In both, the engine is 4-cylinder, rated at 12 Hp. It has an automatic speed governor, dry plate clutch, and 4-speed gear box. Diameter of driving wheels is 21 in.; of steering wheel, 15 in. Tires are solid rubber or pneumatic. A condensing muffler prevents escape of hot gases. A larger 4-wheel tractor has a draw-bar pull of 3600 lb. in low gear and a turning radius of 108 in. Diameter of driving wheels is 32 in.; of steer wheels, 24 in. The motor is rated at 40 Hp. The chassis of this machine can be provided with a shovel or a crane. The crane tractor has an 18-ft. pivoted boom working in one plane that will lift 4000 lb. 12 or 13 ft. from the floor. With boom lowered the machine will go through a 5 × 8-ft. doorway.

Clark Truclifts are made in two models: 1. Front wheel drive with rear wheel steer. 2. Rear wheel drive with 4-wheel steer. The latter will make sharp turns, can be more easily handled in narrow aisles and into and out of box cars. High-lift models will tier 3 ton loads up to 6 ft. high. The lifts are hydraulic. Lifting heads can be fitted with rams or forks like those on some storage battery machines, and the columns can be made to tilt to carry the load safely. Low-lift models will handle loads up to 4 tons.

Tractors for shop use built up around a Ford AA engine are made by Whitehead and Kales Co., Detroit; Mercury Mfg. Co., Chicago; W. F. Hebard & Co., Chicago. These tractors have relatively large rubber-tired wheels, and can travel up to 30 mi. per hr. Some have a box body. Some of the companies named above make gasoline-powered trucks with lift platform to handle U. S. standard skids.

Other gasoline machines suited to outdoor work or on roads have developed from agricultural or road tractors. International Harvester Co., Chicago, makes several types with steel wheels, rubber-tired wheels, or crawler treads. Some can be fitted with digging and excavating buckets, road scrapers, and earth elevators for road work. Similar machines with caterpillar treads are made by Caterpillar Tractor Co., Peoria, Ill.; Allis-Chalmers Mfg. Co., Milwaukee; J. I. Case Co., Racine, Wis., and others. The Roadmaster (Bucyrus-Erie Co.) is a revolving crane with a luffing boom on the chassis of a commercial tractor, with wheels or crawler treads. The Roustabout crane (Hughes-Keenan Co., Mansfield, O.) is a similar machine. It can be furnished with winch heads or power take-off. With boom lowered it will go through a 5 1/2 × 7 1/2-ft. doorway.

**USE OF GASOLINE-POWERED TRACTOR TRUCKS AND TIERING MACHINES.**—Many statements on p. 23–79, *et seq.*, concerning storage battery equipment, as to methods of handling and storing goods, cost of handling and probable saving, apply also to gasoline equipment. In addition to former statements the following advantages are claimed for gasoline tractors and trucks: 1. They can work 24 hrs. per day and take a fresh supply of fuel in 5 min. or less. 2. The torque of the engine and the use of the clutch exert a strong pull to start heavy loads or get over bad places in floors or paving. 3. They can go almost anywhere, are self-contained and independent of power lines and charging stations. 4. They can travel over streets, public roads, bad floors, rough paving.

The Ready-Power gas-electric unit (Ready-Power Co., Detroit) is a self-contained power plant for use on tractors and trucks designed for storage battery power where time cannot be spared for recharging. It is a 4-cylinder automobile-type gasoline engine, with automatic governor and generator armature instead of a fly-wheel. It will deliver 120 amp. at 36 volts, or 90 amp. at 48 volts, weighs 1000 lb. and fits in the space required by a storage battery.

**PROBABLE SAVINGS BY USE OF TRUCK SYSTEM.**—It is difficult to determine mathematically whether or not the use of any system of mechanical handling will be profitable. The Coes formula, *Trans.* A.S.M.E., vol. xliv, 1923, gives various debit and credit items which should be considered. If proper values are assigned, the justifiable investment and the probable profit based on the assumptions, will be given by the formula. It may happen, however, that indirect savings previously mentioned (p. 23–79) will determine whether or not a materials handling system will pay a profit. The Crockett-Payne paper referred to (p. 23–79) gives explicit data on operation of electric lift-trucks and tractors in twenty plants. All show saving of time and money. In some plants indirect and incidental advantages are most important. For examples of the use of the Coes formula, see Koshkin, Modern Materials Handling, p. 194 (John Wiley & Sons). See also *Matl. Handling and Distrib.*, July, Aug., 1931. The same magazine, in Mar., 1931, describes a case where 11 tractors and 23 trailers costing $27,000 saved $48,000 per year. The plant covered 40 acres, and all haulage was done on a timed schedule. For other cases, see a list of 50 installations in *Matl. Handling and Distrib.*, Jan., 1930.

**ELECTRIC INDUSTRIAL LOCOMOTIVES** are of several types: Overhead-wire, third-rail, storage-battery. For mine work, the first are in most general use. They are low, 4- or 6-wheel structures weighing 5 to 35 tons, for track gages as narrow as 18-in. and with one or two trolley poles. Two are used when rails are not bonded for the return circuit. 250-volt series motors generally are used. Haulage capacity, rated as draw-bar pull, usually is taken as $^1/_5$ of the weight of the locomotive, without excessive heating in the motor. The rating may be reduced to $^1/_2$ the standard rating for steady work on long hauls or steep grades. The pull for mine cars on straight level tracks may be taken at 30 lb. per ton; for grades, at 20 lb. per ton for each 1% of grade. Usual speeds are 6 to 8 mi. per hr. Locomotives of this type are made by the large electric manufacturing companies and by manufacturers [8], [34], [44] (see p. 23–81).

**Advantages of Storage-battery Locomotives** are: It is unnecessary to bond rails or remove rock to make legal clearances for trolley wires. They are safe in gaseous mines, can place cars at the working face, remove loaded cars, and go wherever a track can be laid. If batteries are recharged at night, the day load of the power plant is decreased. For mine service they are made in sizes up to 10 tons; for shifting railroad cars, size may be 50 tons. Shifting locomotives (Atlas Car and Mfg. Co., Cleveland) have draw-bar capacity of 30,000 lb. on sanded track, and have standard couplers in radial pockets to permit passing short-radius curves. They are designed to deliver a draw-bar pull of about $^1/_5$ their own weight, but speed of travel and amount of work available between chargings depend on size and discharge rate of the battery. Performance of different sizes and makes should be compared on this basis.

**STORAGE BATTERIES** are of two kinds: 1. The lead battery (Exide, Electric Storage Battery Co., Philadelphia) is very efficient as a storage of electrical energy, and is used for services requiring heavy rates of discharge. 2. The nickel-iron battery (Edison

Storage Battery Co., Orange, N. J.) is lighter than the lead battery but costs more. From $^1/_3$ to $^1/_2$ the price of a storage-battery locomotive is the cost of the storage battery. In shop tractors and trucks the proportion is about the same. To prolong life of cells and insure steady service it is important to use proper charging equipment. A simple, but wasteful, way is to reduce line current from 110 or 250 volts direct current to battery voltage by rheostat control. A better method is to use a motor-generator set whose current consumption is low, and with which the battery cannot be overcharged.

**COMBINATION LOCOMOTIVES** fitted with both storage batteries and current-collectors also are built. The General Electric Co. has built heavy locomotives with Diesel engine generating plants, storage batteries, and current collectors for railroad switching work. Gasoline locomotives are preferred for some kinds of haulage, as they are independent of a power house, have large radius of travel, and, as compared with steam locomotives, require less attention and use fuel only when working. They are made in sizes up to 30 tons, have 4- or 6-cylinder engines and gear shifts for various speeds. For outdoor work or in mines with good ventilation, the exhaust gases are not objectionable.

Diesel-engine locomotives in 25 and 30 ton sizes, also combination gasoline-electric or Diesel-electric locomotives in 50 and 60 ton sizes, are made. See publications of Fate-Root-Heath Co., Plymouth, O.; Whitcomb Locomotive Co., Rochelle, Ill.

## MANUFACTURERS OF MATERIAL HANDLING EQUIPMENT

In the preceding pages, the manufacturers of the several types of equipment described are referred to by number as follows:

1. Alliance Machine Company, Alliance, Ohio.
2. American Engineering Company, Philadelphia, Pa.
3. American Hoist & Derrick Company, St. Paul, Minn.
4. American Steel & Wire Company, Worcester, Mass.
5. Atlas Car & Manufacturing Company, Cleveland, Ohio.
6. Automatic Transportation Company, Chicago, Ill.
7. Baker-Raulang Company, Cleveland, Ohio
8. Baldwin Locomotive Works, Philadelphia, Pa.
9. Barber-Greene Company, Aurora, Ill.
10. Barrett-Cravens Company, Chicago, Ill.
11. R. H. Beaumont & Company, Philadelphia, Pa.
12. Blaw-Knox Company, Pittsburgh, Pa.
13. Bleichert, Leipzig, Germany.
14. Brown Crane Company, Cleveland, Ohio.
15. Bucyrus-Erie Company, Milwaukee, Wis.
16. Byers Machine Company, Ravenna, Ohio.
17. Chain Belt Company, Milwaukee, Wis.
18. Chisholm & Moore Hoist Corporation, Tonawanda, N. Y.
19. Clark Tructractor Company, Battle Creek, Mich.
20. Cleveland Crane & Engineering Company, Wickliffe, Ohio.
21. Clyde Iron Works, Duluth, Minn.
22. Colson Company, Elyria, Ohio.
23. Curtis Pneumatic Machinery Company, St. Louis, Mo.
24. Easton Car & Construction Company, Easton, Pa.
25. Economy Engineering Company, Chicago, Ill.
26. Electro-Lift, Inc., New York.
27. Elwell-Parker Electric Company, Cleveland, Ohio.
28. Euclid-Armington Corporation, Euclid, Ohio.
29. S. Flory Manufacturing Company, Bangor, Pa.
30. Ford Chain Block Company, Philadelphia, Pa.
31. Fuller-Lehigh Company, Fullerton, Pa.
32. Gillis & Geoghegan, New York.
33. Godfrey Conveyor Company, Elkhart, Indiana.
34. Goodman Manufacturing Company, Chicago, Ill.
35. Grindle Fuel Equipment Company, Harvey, Ill.
36. George Haiss Manufacturing Company, New York.

37. Hanna Engineering Works, Chicago, Ill.
38. Hardinge Company, York, Pa.
39. Harnischfeger Corporation, Milwaukee, Wis.
40. Hayward Company, New York.
41. Industrial-Brownhoist Company, Bay City, Mich.
42. Ingersoll-Rand Company, New York.
43. International Combustion Engineering Corporation, New York.
44. Jeffrey Manufacturing Company, Columbus, Ohio.
45. Kennedy-Van Saun Engineering Corporation, New York.
46. Lamson Company, Syracuse, N. Y.
47. A. Leschen and Sons Company, St. Louis, Mo.
48. Lewis-Shepard Company, Boston, Mass.
49. Lidgerwood Manufacturing Company, New York.
50. Link-Belt Company, Chicago, Ill.
51. Logan Company, Louisville, Ky.
52. Maine Electric Company, Portland, Maine.
53. Marion Steam Shovel Company, Marion, Ohio.
54. Maris Brothers, Philadelphia, Pa.
55. Matthews Conveyor Company, Ellwood City, Pa.
56. Mead-Morrison Manufacturing Company, New York.
57. Mechanical Handling Systems, Inc., Detroit, Mich.
58. Mercury Manufacturing Company, Chicago, Ill.
59. Morgan Engineering Company, Alliance, Ohio.
60. National Equipment Company, Milwaukee, Wis.
61. Northern Engineering Works, Detroit, Mich.
62. Nutting Truck Company, Faribault, Minn.
63. Ohio Locomotive Crane Company, Bucyrus, Ohio.
64. Ohio Power Shovel Company, Lorain, Ohio.
65. Samuel Olson & Company, Chicago, Ill.
66. Orton Crane and Shovel Company, Chicago, Ill.
67. Osgood Company, Marion, Ohio.
68. Page Engineering Company, Chicago, Ill.
69. Palmer-Bee Company, Detroit, Mich.
70. Philadelphia Gear Works, Philadelphia, Pa.
71. Pohlig, Leipzig, Germany.
72. Portable Machinery Company, Clifton, N. J.
73. Raymond Bros. Impact Pulverizer Company, Chicago, Ill.
74. Revolvator Company, Jersey City, N. J.
75. Riley Stoker Company, Worcester, Mass.
76. Robbins and Myers, Inc., Springfield, Ohio.
77. Robins Conveying Belt Company, New York.
78. John A. Roebling's Sons Company, Trenton, N. J.
79. Sauerman Bros., Chicago, Ill.
80. Shaw Electric Crane Company, Muskegon, Mich.
81. Shepard-Niles Crane Company, Montour Falls, N. Y.
82. Specialty Engineering Company, Philadelphia, Pa.
83. Standard Conveyor Company, Ellwood City, Pa.
84. Standard Pressed Steel Company, Jenkintown, Pa.
85. Stephens-Adamson Company, Aurora, Ill.
86. Sullivan Machinery Company, Chicago, Ill.
87. Thew Shovel Company, Lorain, Ohio.
88. Jervis B. Webb Company, Detroit, Mich.
89. Webster Manufacturing Company, Chicago, Ill.
90. Wellman Engineering Company, Cleveland, Ohio.
91. Whiting Corporation, Harvey, Ill.
92. G. H. Williams Company, Erie, Pa.
93. Wright Manufacturing Company, York, Pa.
94. Wright Manufacturing Company, Bridgeport, Conn.
95. Yale and Towne Manufacturing Company, Philadelphia, Pa.
96. J. S. Mundy Company, Newark, N. J.
97. Detroit Hoist and Machine Company, Detroit, Mich.
98. C. O. Bartlett & Snow Company, Cleveland, Ohio.
99. Gifford-Wood Company, Hudson, N. Y.

**HORSEPOWER TRANSMITTED BY SHAFTING.**—For shafts subjected to torsion only, let $d$ = diameter of shaft, in.; $P$ = force, lb., applied on a lever arm at a distance $r$ in. from the axis; $S$ = shearing resistance at outer fiber, lb. per sq. in. Then

$$Pr = \pi d^3 S/16 = d^3 S/5.1 = 0.1963\, d^3 S \quad [1]$$

$$d = \sqrt[3]{5.1\, Pr/S} = \sqrt[3]{P\, r/K} \quad [2]$$

where $K = S/5.1$.

If $N$ = revolutions per minute, the horsepower transmitted is

$$\text{Hp.} = \frac{P\, r\, 2\pi\, N}{33{,}000 \times 12} = \frac{\pi\, d^3\, S \times 2\pi\, N}{16 \times 33{,}000 \times 12} = \frac{N\, S\, d^3}{321{,}000} \quad [3]$$

$$d = \sqrt[3]{321{,}000\ \text{Hp.}/N\, S} = \sqrt[3]{C \times \text{Hp.}/N} \quad [4]$$

where $C = 321{,}000/S$.

In practice, empirical values are given to $S$ and to the coefficients $K$ and $C$ according to the factor of safety assumed, which depends upon the material, on whether the shaft is subjected to steady, fluctuating, bending or reversed strains, on the distance between bearings, etc. The factors of safety generally used in practice are: For head-shafts, 15; for line-shafts carrying pulleys, 10; for small, short shafts, countershafts, etc., 7. For steel shafting of 60,000 lb. per sq. in. tensile strength, the allowable stress $S$ with the above factors would be 4,000, 6,000, and 8,500 lb. per sq. in. respectively, whence the diameters of shafts would be

Head-shafts $$d = \sqrt[3]{80\ \text{Hp.}/N} \quad [5]$$

Line-shafts $$d = \sqrt[3]{53.5\ \text{Hp.}/N} \quad [6]$$

Short shafts $$d = \sqrt[3]{38\ \text{Hp.}/N} \quad [7]$$

Table 2 gives the horsepower transmitted by cold-rolled steel line-shafting.

**DEFLECTION OF SHAFTING.—Linear Deflection.**—For continuous line shafting, it is considered good practice to limit deflection to a maximum of 0.01 in. per foot of length. The weight of bare shafting, in pounds, is $W = 2.6\, d^2 L$. When the shaft is fully loaded with pulleys as is usual in practice, with an allowance of 40 lb. per inch of width for the vertical pull of belts, the load in pounds will be about $W \doteq 13\, d^2 L$. With a modulus of

### Table 2.—Horsepower Transmitted by Cold-rolled Steel Line-shafting

Shafting well supported by bearings 8 to 10 ft. apart, with pulleys located close to bearings.
For turned shafting, multiply the figures in the table by 0.775.
For turned shafting simply transmitting power, without pulleys, or short countershafts, multiply by 1.75.
For turned head shafting, multiply by 0.54.
For cold-rolled head shafting multiply by 0.70.

* Radius on one corner only.

transverse elasticity of 26,000,000, the following equations determine length between bearings to avoid excessive deflection.

For bare shafting, $L = \sqrt[3]{873\,d^2};\ d = \sqrt{L^3/873}$ . . . . . . . [8]

For shafting carrying pulleys, etc., $L = \sqrt[3]{175\,d^2};\ d = \sqrt{L^3/175}$ . . . . . . . [9]

In the foregoing equations $L$ = maximum distance, ft., between bearings for continuous shafting subjected to bending stress only; $d$ = diameter of shafting, in.

**Torsional Deflection.**—Torsional stress is inversely proportional to the velocity of rotation, but bending stress will not be reduced in the same ratio. It, therefore, is not practicable to write an equation covering the whole problem which is sufficiently simple for practical use. The following rules, however, are correct within the range of velocities that usually occur under shop conditions. For continuous shafting, so proportioned as to deflect not more than 0.01 in. per foot of length, allowance being made for the weakening effect of keyseats,

For bare shafts, $d = \sqrt[3]{50\ \text{Hp.}/N};\ L = \sqrt[3]{720\,d^2}$ . . . . . . [10]

For shafts carrying pulleys, etc., $d = \sqrt[3]{70\ \text{Hp.}/N};\ L = \sqrt[3]{140\,d^2}$ . . . . . . [11]

For a more complete discussion of the stresses in shafts, see p. 11–04.

**FLEXIBLE SHAFTING** consists of an inner core of built-up wire coils, brazed or soldered into end fittings, surrounded by a protecting casing. Table 5 gives the horsepower transmitted by flexible shafting at various speeds.

**SHAFT HANGERS** are made of cast iron or pressed steel in a variety of forms by different manufacturers. The frames will accommodate various types of hanger bearings, as ball-and-socket bearings, ball or roller bearings, ring or capillary oiling bearings and plain babbitted bearings. Hangers usually have adjusting screws to adjust the bearing

in a vertical plane, to conform to the desired shaft height. Tables 6 and 7 give the dimensions of typical commercial cast-iron and pressed-steel hangers. The length of the bearing varies with the type. Lengths of the various types which may be used with the hangers of Table 6 are given in Table 4.

**Post Hangers** are used when shafting is to be mounted on building columns. Table 8 gives dimensions of one type of adjustable ball-and-socket post hanger. Table 9 gives the dimensions of rigid post bearings.

**DISTANCE BETWEEN BEARINGS.**—The spacing of hangers for line-shafting depends on the size of shaft and the points at which load is applied. The following figures represent average practice with pulleys placed near the bearings:

| Shaft size, in.... | $^{15}/_{16}$–1 $^{7}/_{16}$ | 1 $^{11}/_{16}$–2 $^{3}/_{16}$ | 2 $^{7}/_{16}$–2 $^{15}/_{16}$ | 3 $^{7}/_{16}$–3 $^{15}/_{16}$ | 4 $^{7}/_{16}$–4 $^{15}/_{16}$ |
|---|---|---|---|---|---|
| Distance between bearings, ft.... | 6 | 8 | 10 | 12 | 14 |

# PULLEYS

## 1. PROPORTIONS OF PULLEYS

**PROPORTIONS OF CAST-IRON PULLEYS** (See also Fly-wheels, p. 11–15).—Pulleys for the transmission of power have been standardized by manufacturers and stock pulleys are available for practically all conditions. The design of pulleys, except for special conditions is not advisable. It usually will prove more economical to consult manufacturers of pulleys for the adaptation of a stock pulley to meet the special conditions.

Text-books on machine design give a number of equations for the proportions of cast-iron pulleys, which give slightly different dimensions. The dimensions of stock pulleys vary but little from the values given by the different equations. The equations most frequently used are those of Unwin, Releaux, and J. W. See. These equations follow.

Let $n$ = number of arms of pulley; $D$ = diameter of pulley; $S$ = thickness of belt; $t$ = thickness of rim at edge; $T$ = thickness of rim at middle; $F$ = width of rim; $B$ = width of belt; $w_h$ = width of arm at hub; $w_r$ = width of arm at rim; $b_h$ = thickness of arm at hub; $b_r$ = thickness of arm at rim; $c$ = amount of crowning; $L$ = length of hub; $M$ = thickness of metal in hub. All dimensions are inches.

Width of rim (Unwin) $F = {}^{9}/_{8}\,(B + 0.4)$ . . . . [1a]

(Releaux) $F = {}^{9}/_{8}\,B$ to ${}^{5}/_{4}\,B$ . . . . [1b]

Thickness of rim at edge, (Unwin) $t = 0.7\,S + 0.005\,D$ . . . [2a]

(Releaux) $t = {}^{1}/_{5}\,w_h$ to ${}^{1}/_{4}\,w_h$ . . . [2b]

Thickness at middle of rim, (Unwin) $T = 2\,t + c$ . . . . . . [3]

Width of arm at hub, (Unwin, single belts) $w_h = 0.6337\,\sqrt[3]{FD/n}$ . . . [4a]

(Unwin, double belts) $w_h = 0.798\,\sqrt[3]{FD/n}$ . . . [4b]

(Releaux) $w_h = (F/4) + (D/20n) + {}^{1}/_{4}$ . [4c]

(See) $w_h = 0.0625\,D + 0.5$ . . . [4d]

Width of arm at rim, (Unwin) $w_r = {}^{2}/_{3}\,w_h$ . . . . . . . [5a]

(Releaux) $w_r = 0.8\,w_h$ . . . . . . . [5b]

(See) $w_r = 0.04\,D + 0.3125$ . . . [5c]

Thickness of arm at hub, (Unwin) $b_h = 0.4\,w_h$ . . . . . . . [6a]

(Releaux) $b_h = 0.5\,w_h$ . . . . . . . [6b]

(See) $b_h = 0.025\,D + 0.2$ . . . . [6c]

Thickness of arm at rim, (Unwin) $b_r = 0.4\,w_h$ . . . . . . . [7a]

(Releaux) $b_r = 0.5\,w_h$ . . . . . . . [7b]

(See) $b_r = 0.016\,D + 0.125$ . . . [7c]

Number of arms, (Unwin) $n = 3 + (FD/150)$ . . . [8a]

(Releaux) $n = {}^{1}/_{2}\{5 + (D/2F)\}$ . . . [8b]

Length of hub, (Unwin) $L = {}^{2}/_{3}\,F$ or $2.5\,S$, min. . . [9a]

(Releaux) $L = B$ for single arm pulleys

$= 2\,B$ for double arm pulleys [9b]

Thickness of metal in hub, (Releaux) $M = w_h$ to ${}^{3}/_{4}\,w_h$ . . . . [10a]

Crowning, (Unwin) $c = {}^{1}/_{24}\,F$ . . . . . . . [10b]

The number of arms is arbitrary and may be altered if necessary. Commercial stock pulleys usually are made with four arms up to 10 in. diameter, 6 arms from 11 to 74 in. diameter, and 8 arms for larger diameters. Pulleys with two or three sets of arms may be considered as two or three separate pulleys combined in one. Releaux states in such cases that the proportions of the arms should be 0.8 or 0.7 those of single-arm pulleys.

**Width of Pulley in Relation to Belt Width.**—An equation that is widely used for proportioning the face of pulleys in relation to the width of belt was published by Carl G. Barth (*Am. Mach.*, Feb. 11, 1915). If $F$ and $B$ = respectively, the width of pulley and belt, in.,

$$F = 1.1875\,B + 0.375 \qquad [11]$$

If limits of design make these proportions impractical, the following equation may be used:

$$F = 1.09375\,B + 0.1875 \qquad [12]$$

**Crowning of Pulleys** is necessary to hold the belt central on the face of the pulley, since a belt tends to climb to the largest diameter over which it runs. Different authorities give values for the height of crown $C$ ranging all the way from 0.1 $F$ to 0.011 $F$. Barth uses the equation

$$C = 0.03125\,F^{2/3} \qquad [13]$$

Notation is the same as in the preceding equations.

**STEEL SPLIT PULLEYS.**—Split pulleys made of pressed steel with the arms riveted to the circumference and to the hub are widely used for power transmission. They have the advantages of high strength and light weight. They are available in standard sizes from 3 in. diameter by 3 in. face to 144 in. diameter by 36 in. face, with bores ranging from 1 7/16 to 8 7/16 in. diameter. Pulleys up to 96 in. diameter are made with 6 arms. Larger pulleys have 8 arms.

**WOOD-FACE PULLEYS.**—Pulleys made entirely of wood, or cast-iron pulleys with a wood face, are used where lightness and high belt traction are desirable. Pulleys made entirely of wood are available from 3 in. diameter by 12 in. face to 120 in. diameter by 24 in. face, with bores ranging from 1 1/2 to 7 1/2 in. Their weight is approximately 1/3 that of cast-iron pulleys of similar dimensions.

Wood-faced pulleys are used with high surface speeds and heavy loads. The high coefficient of friction of the wood face insures a more uniform speed and greater tractive effort than is possible with a metal face pulley. They are made both solid and split in sizes from 8 in. diameter by 3 in. face to 72 in. diameter by 40 in. face.

**RELATIVE CAPACITY OF DIFFERENT TYPES OF PULLEYS.**—In an investigation to ascertain the value of compressed spruce pulleys, Prof. G. S. Wilson (Bulletin No. 10, Univ. of Wash. Engg. Expt. Station, 1920) found the horsepower capacity of several different types of pulleys to be as given in Table 1. In this investigation the slip of the belt was measured at belt tensions ranging from 37 1/2 to 187 1/2 lb. per sq. in. of belt section, and the horsepower determined by a Prony brake. The pulleys used in the investigation were 18 in. diam. and 6. in. face.

A paper by Lawrence Whitcomb (Nat'l Assoc. of Cotton Mfrs., 1909) gives the results of tests made at the Lowell Textile School on the relative transmitting capacity of wood-rim, wood-rim with cork inserts, wood-rim lagged with leather, and steel pulleys, all 18 in. diam. by 6 in. face. The results of the tests are summarized in Table 2.

**WEIGHT OF CAST-IRON PULLEYS.**—Table 3 gives the weight of solid cast-iron single-arm pulleys. The values given are approximate and will vary with changes in bore. For split pulleys, the figures in Table 3 should be increased by 10%, and for split-hub pulleys by 4%. The weights of multiple arm pulleys are approximately as follows:

**Table 1.—Horsepower Capacities per Inch Width of Belt of Various Pulleys**

| Pulley | Weight, lb. | Slip of Belt | | | Relative Capacity at 2% Slip |
|---|---|---|---|---|---|
| | | 1% | 1 1/2% | 2% | |
| Kind | | Horsepower | | | |
| Cast-iron | 65.0 | 0.58 | 0.69 | 0.74 | 100.0 |
| Steel | 40.0 | .71 | .78 | .81 | 109.4 |
| Wood split | 21.5 | .63 | .77 | .82 | 110.8 |
| Paper | 41.5 | .62 | .76 | .83 | 112.1 |
| Compressed spruce | 22.0 | .76 | .81 | .84 | 113.5 |

**Table 2.—Tests of Lagged and Cork Insert Pulleys**

| Type of Pulley | Hp. at 2% Slip | Maximum Hp. Transmitted | Slip, percent at Maximum Hp. | Relative Value at 2% Slip |
|---|---|---|---|---|
| Wood-rim pulley with cork inserts | 11.8 | 13.2 | 4.6 | 100% |
| Wood-rim pulley, leather lagged | 8.7 | 12.4 | 4.7 | 73% |
| Steel pulley | 8.3 | 12.7 | 6.0 | 70% |
| Wood-rim pulley | 7.8 | 9.6 | 4.3 | 65% |

Double arm pulley, 2.5 $F/2$; triple arm pulley, 3.75 $F/3$; quadruple arm pulley, 5 $F/4$, where $F$ = width of face of pulley.

**PULLEY WINDAGE.**—The loss of power due to windage of pulleys, *i.e.*, fanning of the air by the pulley arms, may be considerable in transmissions involving a large number of pulleys. The windage varies widely with different types of pulleys. Tests made at

Purdue Univ. to determine the windage loss of cast-iron pulleys and two different types of wood pulleys are reported in *Power*, May 1, 1917. The pulleys were 24 in. diam. by 6 in. face. Following are the horsepower losses due to windage at various speeds:

| R.P.M. | Cast-iron Pulley | Wood Pulley *A* | Wood Pulley *B* |
|---|---|---|---|
| 232 | 0.0042 | 0.0046 | 0.00345 |
| 323 | .0048 | .0120 | .0058 |
| 417 | .0078 | .02585 | .01535 |
| 508 | .0192 | .0443 | .02745 |

Steel pulleys usually have less windage loss than cast-iron pulleys.

**SHAFT SPEEDS WITH VARIOUS DIAMETERS OF PULLEY.**—Let $N$, $n$ = respectively, rev. per min. of driving and driven shafts; $D$, $d$ = respectively, diameter of driving and driven pulleys, in.; $V$ = velocity of belt, ft. per min. Then $DN = dn$; $D = dn/N$; $d = DN/n$; $n = DN/d$; $N = dn/D$; $V = \pi DN/12 = \pi dn/12$.

## 2. CONE PULLEYS

Cone pulleys for driving machine tools should be so designed that the speeds will be in geometrical progression, that is, each speed is the product of the next lower speed and a constant multiplier. According to Carl G. Barth (*Am. Mach.*, Jan. 11, 1912) the ideal ratio of speeds is $\sqrt[4]{2} = 1.189$.

Three general cases exist in the design of cone pulley drives. 1. Crossed belts. 2. Open belts, where the pulleys are so far apart that it is unnecessary to compensate for the tendency of the changing angle to alter the length of the belt. 3. Open belt, with the pulleys so close together that the change in the angle tends to alter the length of the belt, which tendency must be compensated. Inasmuch as in crossed belts the length of the belt is constant, and with open belts with long center distances, nearly so, it is only necessary that the sum of the diameters of the corresponding steps on the mating cones be constant. In case 3, the length of the belt is a function of both the sum and difference of the diameters of the pulleys and a simple solution is not possible. A large number of graphical methods for determining the diameters of the several steps of the pulleys are given in Halsey's Handbook for Machine Designers. A graphical method and a trigonometrical method derived from it are given by C. A. Smith (*Trans.*, A.S.M.E., x, 269).

A slight error, however, in a graphical solution on a small scale may result in a serious error in the size of the pulleys, and a mathematical solution is preferable.

An algebraic solution was derived by William Kent from Burmeister's graphical solution ("*Lehrbuch der Kinematic*"; *Mach'y* Reference Series, No. 14, 1908), which give results far more accurate than are required in practice. In all cases 0.8 of the thickness of the belt should be subtracted from the calculated diameter to obtain the actual diameter of the pulley. This should be done because the belt drawn tight around the pulleys is not the same length as a tape-line measure around them.

The algebraic solution of the problem leads to the following equations:

Let $L$ = distance between the centers; $r_0$ = radius of steps of equal diameter on the two cones; $r_1, r_2$ = radii of any pair of steps; $a = (0.79057\,L - r_0)$. If $r_1$ is given,

$$r_2 = \sqrt{1.25\,L^2 - (0.79057\,L - r_0 + r_1)^2} - 0.79057\,L + r_0. \quad . \quad . \quad . \qquad [14]$$

If the ratio $r_2 \div r_1$ is given, let $r_2/r_1 = c$: $r_2 = cr_1$.

We then have $$a + cr_1 = \sqrt{R^2 - (a + r_1)^2}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \qquad [15]$$

which reduces to $$(1 + c^2)r_1^2 + 2\,a(1 + c)r_1 = 1.25\,L^2 - 2\,a^2, \quad . \quad . \quad . \quad . \quad . \quad . \qquad [16]$$

a quadratic equation, in which $a = 0.79057\,L - r_0$. Substituting the value of $a$ we have

$$(1 + c^2)r_1^2 + (1.58114\,L - 2\,r_0)\,(1 + c)r_1 = 3.16228\,Lr_0 - 2\,r_0^2, \quad . \quad . \qquad [17]$$

in which $L$, $r_0$ and $c$ are given and $r_1$ is to be found.

Let $L = 100$, $c = 4$, $r_0 = 12.858$.

Then $17\,r_1^2 + 10\,ar_1, = 12{,}500 - 8764.62$, from which $r_1 = 5.001$, $r_2 = 20.004$.

If $c = 3$, $r_1 = 6.304$, $r_2 = 18.912$. If $c = 2$, $r_1 = 8.496$, $r_2 = 16.992$.

Checking the results by the approximate formula for length of belt, *viz.*, Length = $2\,L + \pi(r_1 + r_2) + (r_2 - r_1)^2 \div L$, we have

for $c$ = 1, 200 + 80.79 + 0 = 280.79
2, 200 + 80.07 + 0.72 = 280.79
3, 200 + 79.22 + 1.59 = 280.81
4, 200 + 78.56 + 2.25 = 280.81

The maximum difference is only 1 part in 14,000.

J. J. Clark (*Indust. Eng.*, Aug., 1910) gives the following solution: Using the same notation as before,

$$\frac{(c - 1)^2}{L}r_1^2 + \pi(c + 1)r_1 = 2\pi r_0, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \qquad [18]$$

$$\pi(c + 1)r_1 + Lx\left(\frac{60 - 13\,x}{60 - 18\,x}\right) = 2\pi r_0, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \qquad [19]$$

$$x = (r_2 - r_1)^2 \div L^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \qquad [20]$$

The quadratic equation [18] gives the value of $r_1$ with an approximation to accuracy sufficient for all practical purposes. If greater accuracy is for any reason desired it may be obtained by [19] and [20], using in [20] the values of $r_1$ and $r_2 = cr_1$, already found from [18]. Taking $\pi = 3.1415927$, the result will be correct to the seventh figure.

**SPEEDS OF SHAFT WITH CONE PULLEYS.**—If $S$ = speed (revs. per min.) of the driving shaft,

$s_1, s_2, s_3, s_n$ = speeds of the driven shaft,
$D_1, D_1, D_3, D_n$ = diameters of the pulleys on the driving cone,
$d_1, d_2, d_3, d_n$ = diameters of corresponding pulleys on the driven cone,
$SD_1 = s_1\,d_1$; $SD_2 = s_2\,d_2$, etc.
$s_1/S = D_1/d_1 = r_1$; $s_n/S = D_n/d_n, = r_n$.

The speed of the driving shaft being constant, the several speeds of the driven shaft are proportional to the ratio of the diameter of the driving pulley to that of the driven, or to $D/d$.

**SPEEDS IN GEOMETRICAL PROGRESSION.**—If it is desired that the speed ratios shall increase by a constant percentage, or in geometrical progression, then $r_2/r_1 = r_3/r_2 = r_n/r_{n-1} = c$, a constant.

$$r_n \div r_1 = c^{n-1}; \; c = \sqrt[n-1]{r_n \div r_1}.$$

Example.—If the speed ratio of the driven shaft at its lowest speed, to the driving shaft be 0.76923, and at its highest speed 2.197, the speeds being in geometrical progression, what is the constant multiplier if $n = 5$?

Log 2.197 = 0.341830
Log 0.76923 = 1.886056
0.455774

Divide by $n - 1$, = 4, 0.113943 = log of 1.30.
If $D_2/d_2 = 1$, then $D_1/d_1 = 1 \div 1.3 = 0.769$; $D_3/d_3 = 1.30$; $D_4/d_4 = 1.69$; $D_5/d_5 = 2.197$.

# BELT DRIVES

## 1. THEORY OF POWER TRANSMISSION BY BELTING

**BELT TENSIONS.**—A pulley is driven by a belt by means of the friction between the surface of the belt in contact with the pulley. The driving force is the difference between the tension $t_1$ in the tight side of the belt and the tension $t_2$ in the slack side; that is, $p = t_1 - t_2$, where $p$ = effective pull of the belt in pounds. With a given sum of the tensions $t_1 + t_2$, the limit of the tractive force $p$ without serious or objectionable slipping of the belt on the pulley depends upon the length $\alpha$ of the belt in contact with the pulley and upon the coefficient of friction $f$. $\alpha$ is expressed in radians. The value of the coefficient $f$ is discussed below. The relation existing between the quantities $t_1$, $t_2$, $f$ and $\alpha$ is expressed by the exponential formula

$$t_1/t_2 = e^{f\alpha}.$$

Carl G. Barth (*Trans.*, A.S.M.E., xxxi, p. 29, 1909) has developed a theory of belting which is as follows: In considering the formulas which are based primarily on Taylor's investigations on belting (see below), the following assumptions are made: 1. The pulling power of a belt depends on the tension in belt when it is at rest, that is, on the initial tension. 2. The belt in service stretches and thereby decreases the initial tension. The stretch is rapid when the belt is first put up and decreases in amount with the age and service of the belt. 3. A belt whose initial tension is allowed to fall below a predetermined figure will, at a given belt velocity, fail to transmit the desired horsepower. 4. Excessive unit tension in a belt will cause it to stretch rapidly and will increase the maintenance and other charges relating to it. 5. Heavy belts at moderate tensions will give better service than light belts at higher tension. 6. From the standpoint of belt maintenance, the intervals during which belts, running at different velocities and transmitting different horsepowers, will fall to the minimum allowable unit tension and require retightening, should be equalized as far as possible. Belts that are readily accessible can be taken down and retightened more easily than belts in inaccessible locations and, therefore, can be run at higher tensions. An initial unit tension of 200 lb. per sq. in. is about the maximum that should be put upon a belt if it is to be used under the most economical conditions.

**Notation.**—$t_1$ = tension in the tight strand of the running belt, lb. per sq. in.; $t_2$ = tension in the slack strand of the running belt, lb. per sq. in.; $t_0$ = minimum initial tension in the belt at rest on its pulleys, lb. per sq. in. This is the tension to which the belt can be allowed to fall before retightening. $t_m$ = maximum initial tension in the belt at rest upon its pulleys, lb. per sq. in. This is the tension to which the belt is retightened. $t_c$ = centrifugal tension in belt, or loss in effective tension due to centrifugal force, lb. per sq. in.; $p$ = effective pull in belt, lb. per sq. in.; $\alpha$ = arc of contact of the belt on the smalle pulley, in radians = $(\pi/180) \times$ degrees of arc; $f$ = coefficient of friction between belt an pulley; $V$ = velocity of belt, ft. per min.; $e$ = base of Naperian system of logarithms = 2.71828; $A$ = a constant, whose values range from 160 to 320 as explained below.

$p = t_1 - t_2$, . . . . . . . [1]; $t_1 + {}^1/_2\, t_2 = A$ . . . . . . . . [2

For machine belts $A$ = 240 and 320, depending upon whether the values of $t_0$ or $t_m$ respectively, are being sought, as explained later. For countershaft belts, $A$ = 160 an 240, respectively, for values of $t_0$ and $t_m$.

The passage of the belt around the pulley develops a centrifugal force in the belt whic decreases the tension in each strand of the belt, that is, the effective tensions are $(t_1 - t_c$ and $(t_2 - t_c)$ for the tight and slack strands, respectively. The total friction of the bel on the pulley is the ratio of the effective tensions, whence

$(t_1 - t_c) \div (t_2 - t_c) = e^{f\alpha}$ . . . . . . . . . . [3

For the expression $e^{f\alpha}$ may be substituted the expression $10^{0.00758 f\theta}$, where $\theta$ is the arc o contact in degrees. This permits the use of the common system of logarithms instead o the Naperian system. This equation may be interpreted as: The ratio of the effectiv tensions is the number whose common logarithm is $0.00758\, f\theta$.

The centrifugal tension developed at any velocity is

$t_c = 0.000\,003\,454\, V^2$ . . . . . . . . . . . [4 and the coefficient of friction is found from the equation

$$f = 0.54 - \{140/(500 + V)\} \quad . \; . \; . \; . \; . \; . \; . \; . \; [5]$$

Combining the foregoing equations 1, 2, 3, 4 and 5, we obtain the equation expressing the value of $p$ directly in terms of $f$, $\alpha$, $A$ and $V$ as

$$p = \frac{(e^{f\alpha} - 1)\,(2A - 0.000\,010\,36V^2)}{2e^{f\alpha} + 1} \quad . \; . \; . \; . \; . \; . \; [6]$$

which may be expressed as

$$p = \frac{(10^{0.00758f\theta} - 1)\,(2A - 0.000\,010\,36\,V^2)}{2 \times 10^{0.00758f\theta} + 1} \quad . \; . \; . \; . \; . \; . \; [7]$$

The horsepower transmitted then may be determined from the general equation

$$\text{H.P.} = pV/33{,}000.$$

The value of the initial tension in the belt when it is at rest on the pulleys is connected with the formula for $p$ by means of the equation

$$t_{\text{initial}} = {}^1/_{12}\,\{4A - p + \sqrt{(4A - p)^2 - 9p^2}\} \quad . \; . \; . \; . \; . \; . \; [8]$$

which will give values for $t_0$ and $t_m$, respectively, depending on whether 240 or 320 is substituted for machine belts and 160 or 240 for countershaft belts. If, after having determined the values of $p$, $t_0$ and $t_m$, values of $t_1$ and $t_2$ are desired, they may be found by equations [9] and [10].

$$t_1 = {}^1/_3\,(2A + p) \quad . \; . \; . \; . \; . \; . \; . \; . \; . \; . \; . \; . \; [9]$$

$$t_2 = {}^2/_3\,(A - p) \; . \; . \; . \; . \; . \; . \; . \; . \; . \; . \; . \; . \; . \; [10]$$

These equations are useful if it is desired to determine the initial tension in a horizontal belt which theoretically is slightly different from that which should be used for a vertical belt, to which equation [8] applies. This tension, however, differs so slightly from that of a vertical belt, except in the case of belts of extraordinary length, that there is no practical value in determining it separately. This equation for long horizontal belts is

$$t_{\text{initial}} = {}^1/_4\left\{\sqrt{t_1} + \sqrt{t_2} - \left(\frac{C}{5}\,\frac{t_1 - t_2}{t_1\,t_2}\right)^2\right\}^2 \quad . \; . \; . \; . \; . \; . \; [11]$$

where $C$ = center to center distance of the belts, in., other notation being as above. In using equation [11], $p$ is first determined by equations [6] or [7] and $t_1$ and $t_2$ are then evaluated by equations [9] and [10]. Table 2 has been calculated from these equations.

In earlier discussions of the theory of belting, two important assumptions were made which were found by Mr. Barth to be untrue. These were: (*a*) The sum of the tensions in the two strands of a running belt is constant under any variations in the effective pull. (*b*) The coefficient of friction between the belt and its pulley is constant for any given set of conditions, irrespective of the velocity of the belt. To replace the first of these assumptions, Mr. Barth proved the theorem "Under any variation in the effective pull of the belt, the sum of the square roots of the tensions in the two strands remains constant," and for assumption (*b*) Mr. Barth developed the empirical equation [5] for the coefficient of friction which is discussed below.

**COEFFICIENT OF FRICTION.**—Early writers and experimenters gave constant values for the coefficient of friction between the belt and the surface of the pulley. These varied widely. For instance, Morin gave for oily belts, 0.15; for greasy belts, 0.23; for wet belts, 0.36; for dry belts, 0.56. The experiments of Towne and Briggs in 1868 resulted in a recommendation of $f = 0.42$ as the average of the conditions of belt operation. Releaux gives 0.25, which figure generally has been used in approximate calculations.

Mr. Barth's studies of the experiments of Messrs. Lewis and Bird developed the fact that the coefficient of friction varies with the velocity of the belt and its value may be determined quite closely by equation [5]. Values of $f$ according to this equation, for velocities ranging from 0 to 6500 ft. per min., are given in Table 1.

**Table 1.—Values of the Coefficient of Friction of Leather Belts on Iron Pulleys**

(Barth's Formula)

$V$ = belt velocity, ft. per min.; $f$ = coefficient of friction

| $V$ | $f$ | $V$ | $f$ | $V$ | $f$ | $V$ | $f$ | $V$ | $f$ |
|---|---|---|---|---|---|---|---|---|---|
| 0 | 0.260 | 500 | 0.400 | 1000 | 0.446 | 2000 | 0.484 | 4500 | 0.512 |
| 50 | .285 | 600 | .413 | 1200 | .458 | 2500 | .493 | 5000 | .514 |
| 100 | .307 | 700 | .423 | 1400 | .466 | 3000 | .500 | 5500 | .517 |
| 200 | .340 | 800 | .432 | 1600 | .473 | 3500 | .505 | 6000 | .519 |
| 300 | .365 | 900 | .440 | 1800 | .479 | 4000 | .509 | 6500 | .520 |
| 400 | .384 | | | | | | | | |

**WORKING TENSIONS.**—The formulas developed above, and the tables of horsepower calculated therefrom are not based upon the maximum horsepower that a belt can transmit, or on the smallest size of belt that will transmit a given horsepower. Instead, they are designed to give the size and tension of belt that will give the most economical service, first cost, cost of maintenance and repairs, cost of idle equipment due to belt failures, and loss of power due to excessive tensions all being considered.

The foregoing theory is based on the following rule:

For the driving belt of a machine, the initial tension must be such that when the belt is doing the maximum amount of work intended, the sum of the tension on the tight side of the belt and one-half the tension on the slack side will equal 240 lb. per square inch of cross-section for all belt speeds; and for a belt driving a countershaft or one in any other inaccessible location, this sum will equal 160 lb. The maximum initial tension, that is, the tension under which the belt is put upon the pulley when it is placed in service and the tension to which it is to be retightened as often as it falls to the minimum, must be such that the above derived sum is 320 lb. for machine belts and 240 lb. for countershaft belts. These values represent the constant $A$ in the preceding mathematical discussion. Belts in service should be subjected to regular inspection and care. The tension in them should be weighed at intervals and when it falls to the value $t_0$ as given in Table 2, they should be taken down, and a sufficient amount removed from them to restore them to the original initial tension $t_1$.

## 2. HORSEPOWER OF LEATHER BELTS

**ARC OF CONTACT.**—Equation [3] shows that the pull of a belt, and consequently the horsepower transmitted, is a variable depending on the arc of contact of the belt on the pulley. If $\theta$ = arc of contact, $R$ and $r$ = the radii of the larger and smaller pulleys, respectively, $L$ = the center to center distance of the pulleys, all in inches, and $\alpha = \sin^{-1}(R - r)/L$, then, on the large pulley

$$\theta = (180 + 2\alpha) \text{ deg.} \qquad [12]$$

On the small pulley

$$\theta = (180 - 2\alpha) \text{ deg.} \qquad [13]$$

For crossed belts the value of $\theta$ for both pulleys is found by equation [12].

The length of belt $L_b$ in contact with the pulleys of open belts is

$$\text{Large pulley, } L_b = R(\pi + 0.0349 \sin^{-1}\alpha) \qquad [14]$$

$$\text{Small pulley, } L_b = r(\pi - 0.0349 \sin^{-1}\alpha) \qquad [15]$$

With crossed belts, equation [14] applies for the large pulley. For the small pulley, the equation becomes

$$L_b = r(\pi + 0.0349 \sin^{-1}\alpha) \qquad [16]$$

**HORSEPOWER OF LEATHER BELTS.**—Table 2 has been calculated from the Barth equations for both machine and countershaft belts. The arc of contact used is the arc on the smaller pulley, which determines the amount of power that can be delivered to or by the belt. The tables not only show the power that can be transmitted per square inch of cross-sectional area of belt, but also the limits of tension between which the belt should be used in order to transmit the desired power. The values of initial tension $t_m$ are the tensions to which the belt should be tightened when it is put up, and the values of minimum tension $t_0$ are the values below which the tension should not be allowed to fall without retightening.

To use the table, ascertain the arc of contact of the belt on the smaller pulley, by means of equations [12] to [16], and in the section of Table 2 most nearly corresponding to this arc read the horsepower opposite the belt velocity. Multiply the figure so found by the cross-sectional area of the belt in square inches. For velocities other than those in the table, horsepower may be taken as proportional to the velocity. Similarly, the values of the initial and minimum tensions may be taken as proportional to the velocities, care being used to observe whether the consecutive values of the tension as given in the table on either side of the intermediate velocity are increasing or decreasing due to the effect of centrifugal force.

To ascertain the size of belt that will be required to transmit a given horsepower, find from the table the horsepower that a belt of 1 sq. in. cross-sectional area will transmit under the given conditions of speed and arc of contact. Divide the figure so found into the required horsepower, to find the cross-sectional area of the belt. From Table 5 find the maximum width of belt that can be used on the pulleys which are to be used, and divide this width into the cross-sectional area to ascertain the thickness.

**Manufacturer's Ratings.**—Tables of horsepower transmitted by leather belting now (1937) issued by belt manufacturers show, as a rule, greater capacity than the values given

(*Continued on page* 24–19)

**Table 2.—Horsepower and Tension of Belts per Sq. In. of Cross-section**

| | Velocity of Belt, ft. per min. | Machine Belts | | | | | | Countershaft Belts | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | Horsepower | Initial Tension, lb. per sq. in., $t_m$ | Minimum Tension, lb. per sq. in., $t_0$ | Tension, Tight Side, lb. per sq. in., $t_1$ | Tension, Slack Side, lb. per sq. in., $t_2$ | Effective Pull, lb. per sq. in., $t_1 - t_2$ | Horsepower | Initial Tension, lb. per sq. in., $t_m$ | Minimum Tension, lb. per sq. in., $t_0$ | Tension, Tight Side, lb. per sq. in., $t_1$ | Tension, Slack Side, lb. per sq. in., $t_2$ | Effective Pull, lb. per sq. in., $t_1 - t_2$ |
| 180 Degrees Arc of Contact | 250 | 1.05 | 183.75 | 127.5 | 206.0 | 67.9 | 138.1 | 0.70 | 141.0 | 85.0 | 137.3 | 45.3 | 92.0 |

**Table 3.—Service Factors for Belt Installations**

To be used in connection with Table 4

| Type of Equipment | Service Factor | Type of Equipment | Service Factor |
|---|---|---|---|
| Brick and clay machinery | 1.2–1.3 | Pulp and paper | 1.2–1.4 |
| Coal mining machines | 1.0–1.4 | Pumps and compressors | 1.2–1.3 |
| Cotton ginning | 1.0–1.2 | Rock crushing | 1.2–1.4 |
| Fans and blowers | 1.2–1.4 | Textile | 1.2–1.5 |
| Flour and feed mill | 1.2–1.3 | Woodworking | 1.2–1.3 |
| Laundry | 1.1–1.2 | Additional factors for type of motor* | |
| Machine tools | 1.0–1.3 | Reversing or line-start | 1.25 |
| Metal mining | 1.0–1.4 | High-torque A.C. or Compound-wound D.C. | 1.50 |
| Oil field | 1.2–1.5 | | |
| Printing | 1.0–1.3 | | |

* To be applied in addition to the factors for type of equipment.

(*Continued from page* 24–16)

in Table 2. Two reasons exist for this discrepancy. 1. Improvements in tanning and in methods of manufacture have produced more flexible belts with a higher initial coefficient of friction than that of belts made prior to 1930. 2. As noted above, the values of Table 2 are based, not on the maximum horsepower that can be transmitted by a belt, but on the conditions that will give maximum life of belt and minimum cost of service. In the use of the more modern belts, the same considerations should apply.

Table 4 is condensed from one issued by the Graton & Knight Co., and is typical of 1937 belting practice. It is used in connection with Table 3 and the correction factor chart, Fig. 1. A belt must be proportioned to pull loads in excess of the normal rated horsepower of the drive. The increase in horsepower depends on the type of load and the characteristics of the driving motor. Table 3 gives correction factors for various classes of service. Fig. 1 gives correction factors to be applied to the values of Table 4 to compensate for variation of the arc of contact from 180 deg.

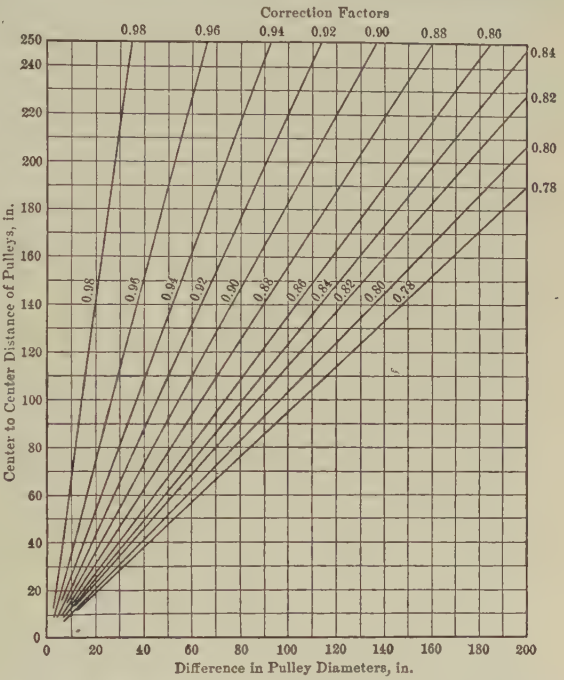

FIG. 1. Factors for Arc of Contact. To be used with Table 4

**Table 4.—Horsepower Transmitted by Leather Belting**

(180 deg. arc of contact)

NOTE.—This table should be used in connection with Table 3 and Fig. 1

| Belt Velocity, ft. per min. | Single Belt | | Double Belt | | | Triple Belt | | Belt Velocity, ft. per min. | Single Belt | | Double Belt | | | Triple Belt | |

**Example.**—A compressor is to be driven by a 5-Hp. high-torque, line-start motor. Motor pulley, 5 1/4 in. diam., 1160 r.p.m. Compressor pulley, 20 in. diam. Center to center distance, 40 in. Required the width and type of belt necessary.

The belt speed is 1594 ft. per min., or say 1600 ft. From Table 4, the heaviest belt that can be used on a 5 1/4-in. pulley is a single belt, 13/64 in. thick. At 1600 ft. per min., the normal capacity of this belt is 3.4 Hp. per inch of width. Difference in the pulley diameters is (20 − 5 1/4) = 14 3/4 in. From Fig. 1, the correction factor for arc of contact is 0.94. The horsepower transmitted by the belt then is 3.4 × 0.94 = 3.2. From Table 3, the service factor for compressors is taken as 1.3. Additional correction factors of 1.25 for line start, and of 1.50 for a high-torque motor, therefore, must be applied. The rated horsepower of the motor is multiplied by these factors to find the maximum horsepower for which the belt must be selected. This figure, divided by the rated capacity of the belt, gives the width of belt necessary, as follows:

$$5 \times 1.3 \times 1.25 \times 1.50/3.2 = 3.8 \text{ in.},$$

or, say, a 4-in. single belt, 13/64 in. thick.

**Table 5.—Width of Pulley to be Used with a Given Width of Belt**

(Table calculated from Barth's formulas. See page 24–09.)

## 3. BELT MAINTENANCE

Correct maintenance of leather belts requires that tensions be held within predetermined limits, and that they be cleaned and greased at regular intervals. Further, regular inspection of belts and pulleys will indicate when belts should be shortened, and also reveal conditions that tend to destroy or damage belts, and permit them to be corrected before harm is done.

**BELT BENCH.**—A convenient method of obtaining the correct tension in belts is the use of a belt bench. This consists of a work bench, of length exceeding the longest center-to-center distance of any belt drive in the shop. On the face of the bench are mounted two non-rotatable pulleys about 18 in. diameter. One of these is fixed. The other is so mounted that it can be moved to any point in the length of the bench, and there locked in position. A scale on the bench reads from zero at the center of the fixed pulley. The reading on the scale opposite the movable pulley is the length of the belt that then can be put around the two pulleys.

In using the bench, the movable pulley is placed at a point on the scale that corresponds to the length of the belt. This length is determined by measurement with a steel tape around the actual pulleys on which the belt is to be used. The belt is placed over the belt bench pulleys, and drawn up to the proper tension by belt clamps. See Fig. 2. The belt clamps are connected by spring balances, one end of each balance being attached to the clamp on the short end of the belt. The other end of each balance is attached to a long draw bolt which passes through the clamp on the long end of the belt. As

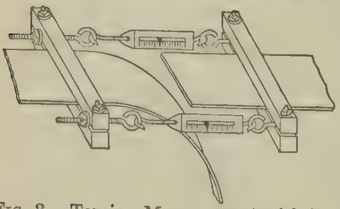

Fig. 2. Tension Measurement with Belt Clamps and Spring Balances

the draw bolts are screwed up by the nuts, the tension in the belt increases and is read on the balances. When the desired tension has been put in the belt, the point where the end of the belt overlaps the main part is marked. The proper addition for lap (see p. 24–23), or deduction for hinge joint is made, and the belt cut off. When the joint has been made, the belt can be placed on the pulleys of the drive, and the tension will be the same as was registered on the spring balances of the belt bench.

Belts which have stretched in service, can be shortened and restored to the proper tension at the belt bench in the same manner.

**TIGHTENING OF BELTS.**—To ascertain the amount that is to be taken out of a belt to restore it to its maximum tension, subtract from the maximum tension the tension in the belt before tightening. Find the figure corresponding to this difference at the bottom of the chart, Fig. 3, and run vertically upward on the chart to the line corresponding to the cross-section of the belt. At the left of the chart, opposite the intersection of the tension and the area so found, read the stretch per 18 in. of length of belt. Multiply this figure by the quotient of the length of the belt in inches divided by 18, or of its length in feet divided by 1.5. The result will be the amount that must be taken out of the belt to restore it to its maximum initial tension.

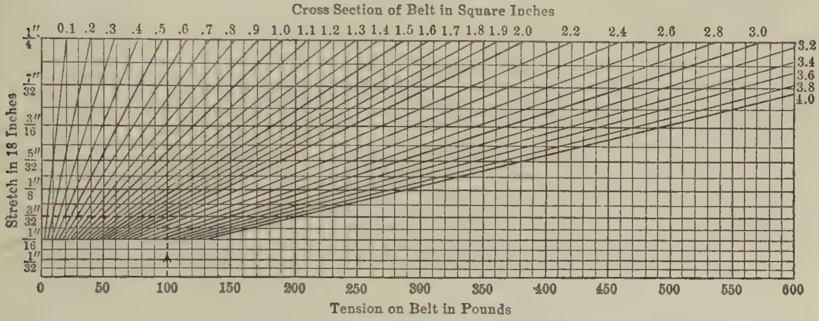

Fig. 3. Tension and Stretch of Belts

Example.—A belt 36 ft. long of 2 in. cross-sectional area shows a total tension of 260 lb. Required the amount by which it must be shortened to restore it to a tension of 360 lb. Increase in tension = 360 − 260 = 100 lb. Enter chart on ordinate of 100 lb. tension, and follow it until it intersects the 2-in. cross-sectional area diagonal. On the scale at the left, opposite this intersection read $^3/_{32}$ in. Then

$$^3/_{32} \times {}^{36}/_{1.5} = 2\,{}^1/_4 \text{ in.} = \text{amount to be taken from belt.}$$

**CLEANING OF BELTS.**—Every precaution should be taken to prevent belts in service becoming saturated with lubricating oil, or, in fact, from coming in contact at all with any kind of oil. If, however, a belt does become so saturated it may be cleaned by first scraping it and then packing it in sawdust or other absorbent for several days. A quicker method is to pass the belt between rolls, under pressure, thereby squeezing out the oil which then may be absorbed by powdered chalk. The surface dirt may be removed from belts by wiping them with a cloth moistened with kerosene. This should be done in every case before applying belt grease.

**BELT DRESSING.**—The use of a belt dressing is to increase the coefficient of friction of a belt and thus enable it to pull a heavier load with a given tension. The dressing should be applied only when the belt slips during working hours. Belts which are regularly inspected and whose tensions are maintained in accordance with the figures of Table 2 will seldom slip, and need no dressing except the regular cleaning and greasing every five or six months. If, however, the belt should slip during working hours as a result of neglect or of being subjected to a heavier load than that for which it was intended, a dressing should be applied sparingly to enable it to continue to pull its load until the machine can be shut down and the belt tightened.

The Tabor Manufacturing Co., Philadelphia, recommends the cleaning of belts at intervals of six months and the application of a grease that will give to the surface a clean sticky pulling surface, similar to that which it has when new, due to the oils and grease that it contains. The grease in the new belt becomes exhausted after the belt has been in service for a certain length of time, as the result of heat, friction and atmospheric action, and the application of additional grease is necessary if the belt is to be maintained in a soft and pliable condition. The grease recommended is the same as that put in the new belt by the manufacturers and consists of 2 lb. edible beef tallow and 1 lb. cod liver oil. The tallow is melted and allowed to cool slightly, after which the cod liver oil is added and the mixture stirred in one direction until cold. It should be applied in light coats by means of a camel's hair brush, and only in such quantities as the belt will easily absorb.

**The Use of Rosin** on slipping belts should be absolutely prohibited. While it may temporarily stop the slipping it will in a very short time ruin the belt.

**TAYLOR'S RULES FOR BELTING.**—F. W. Taylor (*Trans.* A.S.M.E., xv, 204) describes a nine-year experiment on belting in a machine shop, giving results of tests of 42 belts running night and day. Some of the belts ran on cone pulleys and others on shifting or tight-and-loose pulleys. The average net working load on the shifting belts was only 0.4 of that on the cone belts. The experiments are summarized below.

Belt tensions were weighed on spring balances between belt clamps when the belts were first put on, and when they were retightened. Belts were so proportioned that the initial tension with the belt at rest was 71 lb. per inch of width of double belt, equivalent to the following stresses, lb. per sq. in.: Oak tanned and fulled belts, 192; oak tanned, not fulled, belts, 229; semi-rawhide belts, 253; rawhide belts, 284. Conclusions drawn from the experiments were:

Belt speeds for maximum economy should be from 4000 to 4500 ft. per min. The best distance from center to center of shafts is 20 to 25 ft. Double belts should be used on pulleys 12 in. diameter or larger; triple belts on pulleys 20 in. diameter or larger; quadruple belts on pulleys 30 in. diameter or larger. Belts are more durable and work more satisfactorily when made narrow and thick, rather than wide and thin. As belts increase in width they should be made thicker. The ends of the belt should be fastened together by splicing and cementing instead of by lacing, wiring or hooks or clamps of any kind. A V-splice should be used on triple and quadruple belts and when idlers are used. A stepped splice, coated with rubber and vulcanized in place is best for rubber belts. Splices in double belts up to 10 in. wide should be 10 in. long. For belts 10 to 18 in. wide, length of splice should be equal to the width of the belt. For belts over 18 in. wide, splice should be 18 in. long. Belts should be cleaned and greased every five to six months. Double leather belts will last well when repeatedly tightened under a stress, when at rest, of 71 lb. per inch of width, or 240 lb. per sq.in. of cross-section, but they will not maintain this tension for any length of time. Idler pulleys work most satisfactorily when located on the back side of the belt about one-quarter of the distance from the driving pulley.

The comparative performance of belts proportioned according to ordinary practice, giving a total load of 111 lb. per inch of width, and belts proportioned to give a total load of 54 lb. per inch of width, are given in Table 6.

Belts of any width can be shifted backward and forward on tight-and-loose pulleys. The best form of belt shifter for wide belts is a pair of rollers twice the width of the belt, either of which can be pressed against the flat surface of the belt on its slack side close to the driven pulley. The axis of the roller should make an angle of 75 deg. with the center line of the belt.

**Conditions that Injure Belts.**—Belts that are running under improper conditions will give certain indications which may be used to identify and correct such conditions. If the tension on the belt is higher than it should be, the outside surface of the belt will tend to crack. If the laps also open up, the belt probably is too thick for the diameter of the pulleys. Ply separation also indicates too thick a belt. A belt cracked and checked on the pulley side indicates excessive slip of the belt. If the belt runs against the flange of a pulley or runs in contact with improperly placed belt shippers or guides, it will curl and the plies will open up on the edge. A belt running in the wrong direction will be indicated by the outside points of the laps opening. Dry rot of the belt indicates lack of dressing, and oil rot indicates exposure of the belt to lubricating oil. A belt too small for the power to be transmitted is indicated by short life both of the leather and of the cement.

## 4. BELT JOINTS

Four methods of joining the ends of belts are in general use, *i.e.*, cementing or gluing (endless belts), rawhide lacing, metal lacing and wire hinge joints. The endless belt is recommended wherever it can be used, but it is difficult to readjust the tension without taking the joint apart, unless the belt runs on pulleys which are adjustable and can be moved apart to compensate for belt stretch. Rawhide lacing, formerly the common method of making belt joints, has largely been replaced by the wire hinge joint. Metallic lacing is comparatively little used, and is not especially suited to belts running on small diameter pulleys.

**ENDLESS BELTS.**—The length of splice depends on the width and thickness of the belt. Table 7 gives the length of splices as recommended by the Graton & Knight Co.

For making the joints, belt manufacturers offer special cements, or the following glue, recommended by the Tabor Mfg. Co., may be used: Two parts liquid fish glue, one part liquid isinglass, by measure. The glue should be applied hot.

Before the joint is made the belt should be placed over the pulleys and drawn up to the proper tension by means of belt clamps, or it should be measured on a belt bench (see p. 24–20). Tension should be measured by spring balances between the clamps. When the belt has been drawn up to the proper tension, its length under tension should be noted and the proper allowance added for lap. The ends of the belt then are scarfed as shown in Fig. 4. The scarfed surfaces should be thoroughly sized with cement or glue and the two ends squeezed together between boards, pressure being applied by means of screw clamps. In using cement, after sizing, the belt joints are cemented a few inches at a time, each application being allowed to set for one half hour before the next section is cemented.

Endless belts should be run so that the feather edge of the splice on the side next to the pulley points away from the pulley as the splice approaches it.

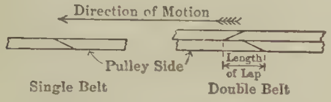

Fig. 4. Belt Laps

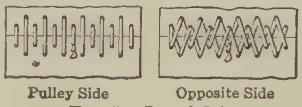

Fig. 5. Laced Joint

**LACED JOINTS.**—The ordinary belt lacing is a strip of rawhide whose width depends on the size of the belt to be laced. The ends of the belt are cut square with the edges and butted together, after which holes are punched in the two ends with an oval punch, the large diameter of the oval being parallel with the sides of the belt. The lacing is started at the center, worked over to one side of the belt, back to the opposite side, and is finally brought to the center at the point at which it started. The lacing is carried out as shown in Fig. 5. The lacing is parallel to the sides of the belt on the face next to the pulley and crossed on the opposite side. Table 8 (A. D. Porter, *Railway Age-Gazette*, Nov. 4, 1910) shows the size of lacing and the punching of the holes for lacing various sizes of belts.

**Table 6.—Performance of Belts under Different Conditions**

| | Total load per inch of width | |
|---|---|---|
| | 111 lb. | 54 lb. |
| | Effective pull per in. of width | |
| | 65 lb. | 26 lb. |
| Shorten double belt to restore tension, in. per 10 ft. of belt | 1/2 | 1 |
| Life of double belt when carefully handled, years | 7 | 18 |
| Cost of maintenance, % of original cost | 37 | 14 |
| Total stretch of belting, % of original length | 6 | 6 |
| Stretch during first 6 months, % of total stretch | 36 | 15 |
| Stretch allowable before retightening, % of original length | 0.47 | 0.81 |
| Interruptions to manufacture per year | 5 | 0.75 |

**Table 8.—Data for Lacing Belts**

| Width of Belt, in. | Punching of Lace Holes, Distance from Ends of Belt, in. | | Distance of Center Line of First Hole in First Row from Edge of Belt, in. | Size of Belt, Lace, in. |
|---|---|---|---|---|
| | First Row | Second Row | | |
| 2 to 4 | 3/8 | 3/4 | 3/8 | 3/16 |
| 6 " 8 | 1/2 | 1 | 1/2 | 1/4 |
| 10 " 12 | 5/8 | 1 1/4 | 5/8 | 5/16 |
| 14 " 16 | 3/4 | 1 1/2 | 3/4 | 3/8 |
| 18 " 20 | 7/8 | 1 3/4 | 7/8 | 7/16 |
| 22 " 24 | 1 | 2 | 1 | 1/2 |

The strength of a laced joint is about one-half that of the belt itself, or about 1000 to 1500 lb. per sq. in.

The objections to the laced joint are that it is seldom well made, and that it is difficult to lace a belt so as to maintain the same tension in it on the two edges of the belt. It also virtually increases the diameter of the pulley at the point at which the joint is in contact with it, since the lacing cannot be made flush with the surface of the belt. The lacing causes the belt on either side of the joint to be raised from the pulley, and destroys the intimate contact of belt and pulley. The joint also is less flexible than the remainder of the belt, and this has a more or less detrimental effect on the belt and the service rendered by it. Belts as a rule fail at or near the lacing. Added to the other objections, the making of a laced joint is slow and expensive.

**METALLIC BELT LACING** consists of a strip of steel cut into a series of Vs. The points of the Vs on each side are bent at right angles to the body of the lacing. The ends of the belt are butted together and a strip of the metallic lacing whose length is equal to the width of the belt is laid across the joint. The points are then driven through the belt, clinched on the pulley side, and driven into the belt so that there will be no projections to come in contact with the pulley as the joint passes over it. The metallic lacing provides a rapid and cheap means of making a joint, but it is less flexible than the rawhide lacing. It is also difficult to break the joint for purposes of repair without seriously damaging the belt at the joint.

**WIRE-LACED HINGE JOINTS.**—The most satisfactory method of making a belt joint, all things considered, is by the use of wire which is looped through each end of the belt in a series of eyelets which project beyond the end of the belt. The eyelets in the two ends are brought together and a pin of rawhide is run through them, thus joining the ends of the belt and forming a true hinge. The finished joint does not project above the surface of the pulley, and as the joint can be bent through an arc of about 270 deg. there is no diminution in the flexibility of the belt as a whole. Machines for making joints of this character are made by the Peerless Belt Lacing Machine Co., Philadelphia, and by the Birdsboro Foundry & Machine Co., Birdsboro, Pa.

The pin should be cut off about $^1/_8$ in. short on each side of the belt. The strength of a joint made in the above fashion is stated to be about 700 lb. per lineal inch of joint. For belts that are to be used in damp places brass, instead of steel, wire is recommended.

## 5. ARRANGEMENT OF BELT DRIVES

**ARRANGEMENT OF PULLEYS.**—If possible, machinery driven from overhead shafting should be so arranged that the belt will make an angle from the vertical of not less than 45 deg. Never, unless it is absolutely impossible to avoid it, should driving and driven pulleys be in the same vertical line. Care should be taken to arrange the pulleys in line with each other, the tops of the crowns being aligned. Otherwise the belt will tend to stretch unevenly and to run crooked. Machinery should be so placed that the tight strand of the belt will be the bottom strand. If, however, machines are so placed that the pull of the belts at alternate line shaft pulleys is in opposite directions, the wear and strain on bearings will be reduced. This arrangement of machinery will make one-half of the belts drive with the top strand tight.

The distance between shafts has considerable influence on the life of belts. Distances should, as a rule, be made as great as possible up to reasonable limits. For narrow belts on small pulleys, a good average figure is 15 ft.; for larger belts the center line distance should be from 20 to 25 ft., while for main belt drives using wide and heavy belts, pulleys should be from 25 to 30 ft. apart. If the distance is made too great the belt will have a tendency to flap and injure itself.

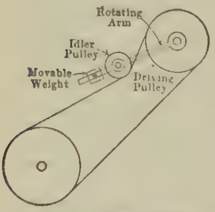

Fig. 6. Idler Pulley

**IDLER PULLEYS.**—Belts which are run on pulleys located close together are liable to stretch rapidly and thus lose the tension necessary to the transmission of the desired amount of power. For such cases, and also for belts which are required to run for long periods without stopping, an idler pulley, which can be moved against the belt to take up the slack and thus increase the tension, will be found desirable. The idler should be located about one-quarter of the distance from the driving pulley and should bear against the slack side of the belt. Its effect is not only to increase the tension, but also the arc of contact. The idler may be so constructed that it can be moved against the belt at will, or it may act automatically by means of a spring or gravity. Such an arrangement is shown in Fig. 6.

**GUIDE PULLEYS.**—Where two shafts that are not parallel and that do not intersect are to be connected by belting, and the conditions are such as to make a quarter-twist belt inadvisable, guide pulleys are used. The function of the guide pulley is to alter the direction of the belt and cause it to run squarely on to the receiving pulley. The location of the guide pulley with reference to the main pulleys is determined by the intersection of the planes passing through the center of the face of the main pulleys and perpendicular to their axes. Thus in Fig. 7, let $A$ and $B$ represent the main pulleys, and $xx$ and $yy$ the planes passed through the middle points of their respective faces. These intersect in the line $CD$. Tangents from any two points as $E$ and $F$ on this line to the points $H$ and $J$, and $G$ and $K$, respectively, on the pulleys $A$ and $B$ will determine proper paths for the belt. The guide pulleys should be located at the intersection of the tangents $HE$ and $EJ$ and $FG$ and $FK$, respectively, and the plane through the center of the face of each pulley should coincide with the planes formed by these tangents. Figs. 8 to 11 show various arrangements of guide pulleys. Others will suggest themselves according to the needs of each particular case. It is only necessary to observe the precaution that the guide pulleys be so placed that they will receive the belt squarely from the main pulley and deliver it squarely to the next one. If this be done, the pulleys may be placed in practically any location and at practically any angle.

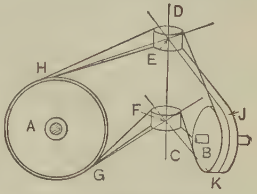

FIG. 7. Guide Pulleys

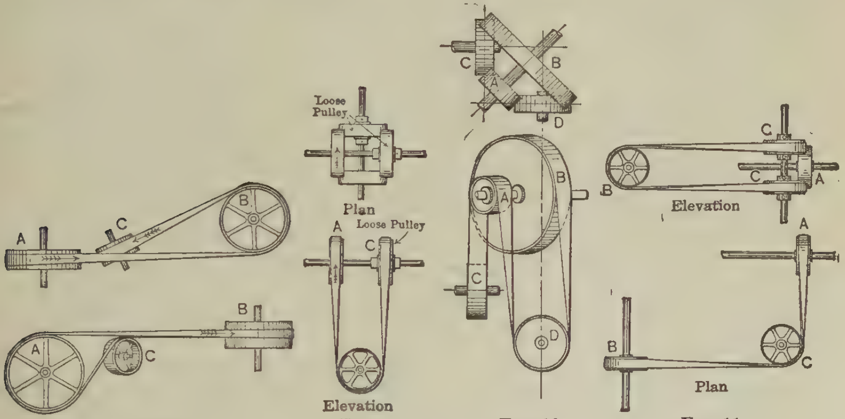

FIG. 8 FIG. 9 FIG. 10 FIG. 11

Drives with Guide Pulleys

**Quarter-Twist Belts.**—One of two shafts at right angles to each other and in different planes may be driven from the other by means of a belt with a quarter twist in it, providing that the distance between the shafts is not too short. The belt must run squarely on to each pulley and the point at which the belt leaves each pulley must lie in the straight line formed by the intersection of the planes passing through the center line of the face of each pulley and perpendicular to their axes, as shown in Fig. 12. The driving pulley is $AD$ and the belt runs in the direction shown by the arrows. The point $C$ at the end of the horizontal diameter of the driven pulley at which the belt leaves it is set so that it is vertically above the point $A$ at the end of the horizontal diameter of the driving pulley where the belt leaves that pulley. Should the shafts in question be respectively a horizontal and a vertical one the relative arrangement of the pulleys would be the same as shown in the illustration. It makes no difference what position the shafts take so long as the leaving points of the belts on the pulleys are in the straight line determined by the intersection of the two planes as described. The quarter-twist has been used with belts up to as much as 30 in. wide. There should be a considerable distance between the shafts, however. For heavy belts and short center line distances, guide pulleys or mule pulley stands should be used. A quarter-twist belt will drive in one direction only.

Where the quarter-twist belt drives through a floor the location of the holes in the floor can be determined by the following method (M. H. Ball, *Machy.*, Sept., 1912) as shown in Fig. 13. From the end of the horizontal diameter at which the belt leaves the upper pulley a plumb line is dropped to the floor, and point *L* on the floor is marked. Through *L* are drawn on the floor the lines *XX* and *YY* respectively perpendicular to the lines of shafting on which the upper and lower pulleys are carried. The outlines of the pulleys in plan are then traced on the floor, these being *aXbdLc* and *efYghL* respectively for the upper and lower pulleys, each being symmetrical about the center lines *XX* and *YY*. These center lines, which are the projections of the horizontal diameters of the pulleys, are next divided into eight equal parts, the divisions being numbered as shown. The numbers should start at the end of the diameters at which the belt runs on the pulley. Next divide the distance in inches between the center lines of the shafts by the number of divisions laid out on the pulley, and the distance from the center line of the upper shaft to the floor by the quotient so obtained. The latter figure represents the number of spaces on the pulley that the belt at the floor will be away from the end of the diameter at which it runs on to the pulleys, that is, the points *J* and *K* in Fig. 13. From *J* as a center with the line *JM*, perpendicular to *XX*, as a radius strike arc *MN*. The arc is divided into eight equal parts and numbered from *M* to *N*. The same number of spaces are taken on the arc as were taken on the lines *XX* and *YY*, and *OP* is drawn through the point *J* and the point on the arc so found, *PJ* being made equal to *JO*. This line is the position of the center line of one strand of the belt at the floor, while a line parallel to *OP* through *K*, and of the same length is the position of the center line of the other strand.

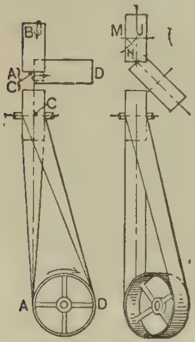

FIG. 12. Quarter-twist Belt

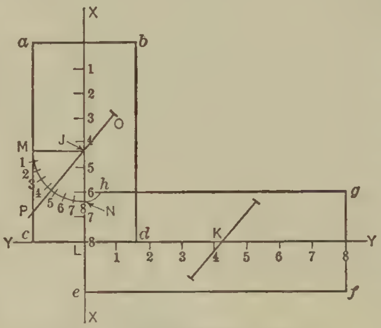

FIG. 13. Laying Out Floor Hole for Quarter-twist Belt

Quarter-twist belts may be used to drive shafts which make angles with one another of other than 90 deg., if the rule is observed that the points at which the belt leaves the pulleys are in the straight line determined as explained previously. The method of laying out holes in the floor is the same as that used for shafts at right angles, except that the arc *MN* on the pulley outline extends only to a line drawn from the point *J* parallel to the face of the lower pulley.

**Mule Pulley Stands.**—A common arrangement of guide pulleys, known as a mule pulley stand, is shown in Figs. 14 and 15. The method followed in locating the pulleys and determining the angles at which they are to be placed is as follows: The pulleys which are to be connected by a belt are *A* and *B*, and they have the relative locations as shown in the various views. The center line *XX* in the elevation is prolonged, and at a distance *L* (see plan) from the line *ZZ* through the middle plane of the face of the pulley *A*, the line *Z′Z′* is drawn. Through the point *p*, the line *YY* is drawn parallel to *XX*, and at a distance below it equal to the vertical distance between the shafts of the two pulleys. With *p* as a center the circle *A′* is drawn with a radius equal to the radius of the pulley *A*. The circles *B* and *A′* are then joined by the tangents *TT′* and *SS′*, which represent the inclination of the belt with respect to the pulleys at all points along its length. At the point *a* where these tangents intersect the line *ZZ* the lines *ab* are drawn parallel to the line *XX*. The diameter of the mule pulleys having been decided, the point *d* is set off on *ab* at a distance from *ZZ* equal to half the diameter of the mule pulley. Through *d* is drawn the line *ef* parallel to *ZZ*. This represents the center of the mule stand. The lines *gh* through the point *d*, perpendicular to the tangent *TT′* or *SS′* will be the axis of the mule pulley. The points *c* and *j* are laid off on either side of the point *d* on the line *gh*, *dc* and *dj*, being made equal to half the width of the mule pulley. The bearings of the mule pulley will lie on the line *gh* outside of the points *c* and *j*, and their position with reference to the center lines of the main pulleys can be ascertained by scaling the drawing or by calculation, as preferred. If the drawing is laid out to a large enough scale, scaling will be accurate enough for all practical purposes. The axes of the mule pulleys will necessarily be inclined from the vertical, not only as regards the plane *ZZ* through the middle of the face of the pulley *A*, as shown in the elevation Fig. 14, but also as regards the plane *WW* through the middle of the face of pulley *B* as shown in Fig. 15, and this angle will be the same in the two views. Lines through the points *c* and *j* parallel to the tangents *TT′* and *SS′* will be the major axes of the ellipses representing the upper and lower sides of the mule pulleys in the two views in Figs. 14 and 15. The position of the center of the mule stand and of the mule pulleys in the end view of the drive, Fig. 15, is determined in exactly the same manner as the similar points in the elevation in Fig. 14, and no further explanation is necessary. The various points in Fig. 15 are designated by the same letters as the corresponding points in Fig. 14, and the same explanation will apply.

If it be borne in mind that the governing principle of mule pulley drives, and in fact of all drives where the belt joins two pulleys that are not in the same plane, is that the belt must be delivered squarely on the pulleys, but that it can leave them at any angle within reasonable limits, it is evident that the mule pulleys can be placed in any location desired. If local conditions make it advisable, the mule pulleys can be so placed as to require the belt to leave either or both of the main driving pulleys in a horizontal position. The method of laying out the drive is the same in any event. The only variation will be in the relative length of the dimensions $L$ and $L'$. The sum of these is taken and the position of the circle $A'$ is then determined as before. The angle of the pulleys will be the same, as will be the length of the belts.

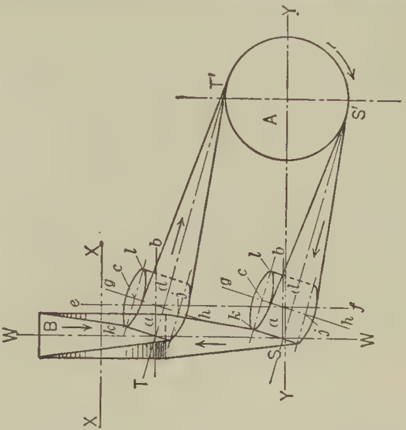

FIG. 15. Mule Pulley Drive

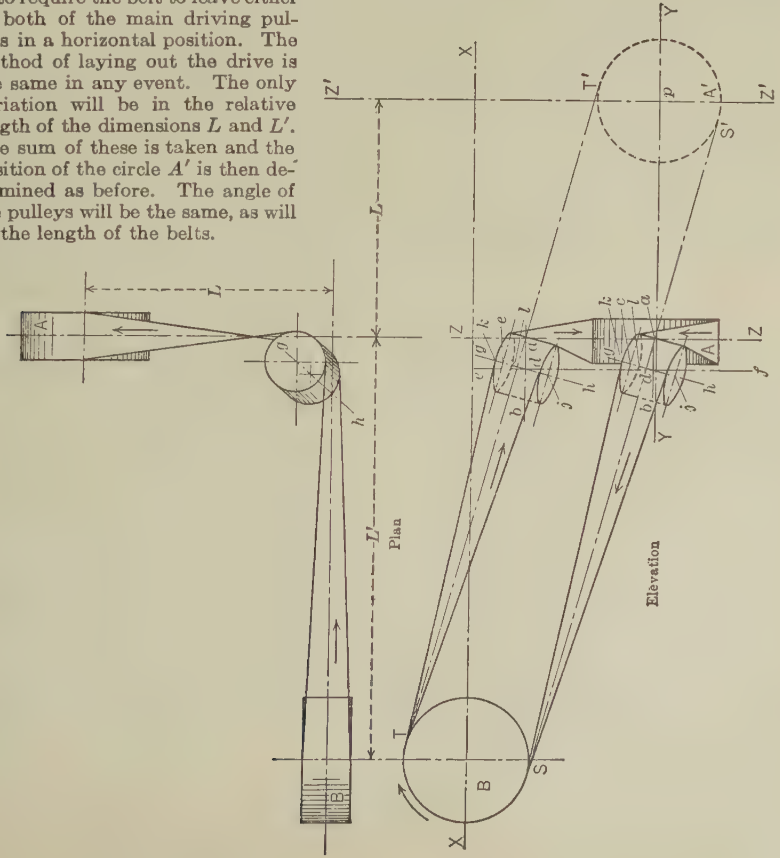

FIG. 14. Mule Pulley Drive

The fact that it is possible to vary the position of the mule pulleys without affecting the working of the drive makes it possible to place both mule pulleys on the same shaft. Referring to Fig. 14, if the belt travels in the direction of the arrows, it is evident that if the lower mule pulley be moved in the direction that the belt travels, the belt will still be delivered squarely to pulley *B*. It will, of course, leave pulley *A* at an angle, but this will have no effect on it if the mule pulley is maintained at the same angle as before, since the belt will still be received squarely by the mule pulley. If the distance between the axes of the mule pulley shafts is not excessive, the lower mule pulley may be moved until the two shafts are in line, as regards Fig. 14. They will, however, still be out of line as regards Fig. 15. By the same process of reasoning as before, however, it is evident that the upper mule pulley can be similarly moved in the direction of the belt travel until its axis is in line with that of the lower pulley in Fig. 15. The axes of the two mule pulleys then will coincide, and in their new locations they can be mounted on the same shaft.

The above considerations apply to drives where the main pulleys are of the same diameter. If they are unequal, the shafts of the mule pulleys will lie at different angles and the pulleys must be mounted on separate shafts. The location of the shafts is determined by the same method as described above, however, the only difference being that the axis of the upper mule pulley is determined by the perpendicular to the tangent $TT'$, Fig. 14, while that of the lower one is determined by the perpendicular to the tangent $SS'$. These tangents in this case will not be parallel. Otherwise the construction is the same as for drives with main pulleys of equal diameter.

## 6. SHORT CENTER DRIVES

Belt drives with flat belts, between shafts whose center lines are but a short distance apart usually prove unsatisfactory unless provision is made to increase the tension in the belt or to give a greater arc of contact on the driving pulley. Increased tension and greater arc of contact may be obtained at the same time by a weighted floating idler (see p. 24–24). Increased tension which automatically adjusts itself to the load is obtained by means of the Rockwood drive (see below). Since 1930 the drive known as the V-belt or Texrope drive has come into wide use for short center drives. Both the V-belt drive and the Rockwood drive may be operated with the driving and driven shaft located in the same vertical plane.

**V-BELT DRIVES.**—The V-belt drive consists of one or more endless belts constructed of cotton cords and fabric impregnated with and imbedded in rubber, and of trapezoidal cross-section. These run on sheaves with V-shaped grooves on the periphery. The angle of the groove depends on the service in which the belt is to be used, and manufacturers of V-belts should be consulted concerning details of a particular drive. The drives are so designed that the belt is approximately flush with the top of the pulley. A clearance is provided at the bottom of the grooves in the sheaves to insure contact with the belt only on the sides of the grooves. These drives will run in either direction, with the slack either on top or bottom strands. They are especially adapted to reversing service. The V-belt was first developed by the Allis-Chalmers Mfg. Co., whose product is sold under the name of Texrope drives. Other manufacturers are the Dayton Rubber Mfg. Co., Dayton, O., Manhattan Rubber Co., Passaic, N. J., Goodyear Rubber Co., Akron, O.

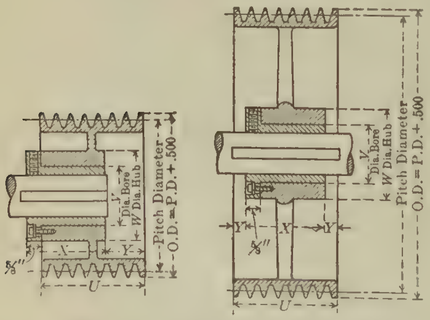

Fig. 16. Texrope Drive Sheaves

Table 9 and Fig. 16 give the dimensions for the sheaves used in connection with the drives listed in Table 12.

The following data were supplied by the Allis-Chalmers Mfg. Co. In the design of Texrope drives provision should be made for peak or shock loads in excess of 100% of full load, by the use of additional Texropes over those required for normal full load operation. Overload factors are as follows:

| | | | | | | |
|---|---|---|---|---|---|---|
| Peak load, percent | 100 | 125 | 150 | 175 | 200 | 250 |
| Overload factor | 1.0 | 1.1 | 1.2 | 1.3 | 1.4 | 1.5 |

The horsepower rating of the motor is multiplied by the overload factor to obtain the normal rating of the required drive. Other factors that must be taken into consideration

are a speed-up factor of 1.2 and a reversing service and line-start motor factor of 1.2. Both these factors are applied in addition to the overload factor if the conditions of the drive require them. A service overload factor, depending on the application of the drive, may be applied instead of the overload factor given above. Service factors are given in Table 10.

Texropes are made in the following sizes of cross-section, the first figure denoting the maximum width and the second the thickness: $1/2 \times 11/32$ in., $21/32 \times 7/16$ in., $7/8 \times 17/32$ in., $1\ 1/4 \times 3/4$ in., $1\ 1/2 \times 1$ in. Selection of the correct drive is made from voluminous tables issued by the manufacturers of V-belts, Tables 11 and 12 being typical of those issued for drives of from 2 to 25 Hp., using cast-iron sheaves. Table 11 gives center distances that are available at various speed ratios of driving and driven sheaves with Texrope drives of the class noted, and also the serial number of the belt that can be used. At the top of each column of center distances the letters A, B, C, and D, refer the user to corresponding columns in Table 12, in which will be found the horsepower that can be trans-

mitted per single Texrope at the given motor speed and selected center line distance. This figure for horsepower is divided into the horsepower required for the drive, the quotient being the number of Texropes that must be used. Since a fraction of a rope cannot be used the next higher integer must be taken when the quotient is a fraction or a mixed

**Table 12.—Horsepower of Texrope Drives with Cast-iron Sheaves**

2 to 25 Horsepower. 21/32 × 7/16-in. Texrope. 2 to 10 Grooves

(Allis-Chalmers Mfg. Co., Milwaukee, Wis.)

| 5.6 | 38.0 | 6.78 | 255 | 2.40 | 2.48 | 2.54 | 2.54 | 168 | 1.60 | 1.66 | 1.69 | 1.69 | 125 | 1.22 | 1.27 | 1.30 | 1.30 |
| 5.4 | 38.0 | 7.04 | 246 | 2.34 | 2.42 | 2.48 | 2.48 | 162 | 1.54 | 1.59 | 1.63 | 1.63 | 121 | 1.19 | 1.23 | 1.26 | 1.26 |

number. It should be noted that the horsepower required for the drive is the maximum horsepower after all overload factors have been applied.

Example.—A fan operating continuously at 400 r.p.m. is to be driven by a 10-Hp. 1140-r.p.m. motor. Center distance of fan and motor shafts, approximately 28 in. Required the drive for this installation. *Solution.*—From Table 10, the overload factor for fans is 1.2 to 1.4. For continuous duty the higher value would be used. Horsepower of drive, therefore, is 1.4 × 10 = 14 Hp. Speed ratio = 1140/400 = 2.85. In Table 11, opposite speed ratio 2.86, find in column D a center distance of 28.3 in., which may be assumed as satisfactory. In Table 12, column D under motor speed of 1140 r.p.m., and opposite speed ratio of 2.86 find the horsepower per No. B90 Texrope to be 2.68. Number of texropes required = 14/2.68 = 5.22. Hence, the drive will consist of six No. B90 Texropes. From Table 12, sheave pitch diameters will be 5.6 and 16 in. respectively.

**PIVOTED MOTOR (ROCKWOOD) DRIVE.**—An efficient short-center drive, generally known as the Rockwood drive, uses a flat belt. The driving motor is mounted on a pair of overhanging arms that are free to rotate about a shaft in a base which is rigidly attached to the supporting structure. See Fig. 17. Various arrangements are possible to permit of floor, ceiling, wall or machine mounting. See Figs. 18 and 18*a*. The weight of the motor thus is utilized to provide tension in the belt. The arms are adjustable, permitting movement of the motor toward or away from the rocker shaft, and thus enabling any desired initial tension to be obtained in the belt. As the belt stretches in service, the

weight of the motor automatically takes up the slack developed, and maintains the tension at a constant value. Table 14 and Fig. 19 give the dimensions of standard Rockwood bases and Table 13 gives the size of base that should be used with different sizes of motors under various conditions of driving.

**Theory of the Pivoted Motor Drive.**—R. R. Tatnall (*Mech. Engg.*, May, 1935) outlines the theory of the pivoted motor drives and develops equations to determine the length of lever arm on which the motor is mounted. The tension in the two strands of the belt and the ratio of the tensions is given by the equations

$$T_1 = \{eW/(a + b)\} + bkP/(a + b) \quad \text{[17]}$$

$$T_2 = \{eW/(a + b)\} - akP/(a + b) \quad \text{[18]}$$

$$T_1/T_2 = (eW + bkP)/(eW - akP) \quad \text{[19]}$$

where $T_1$, $T_2$ = respectively, tension in tight and slack strands of the belt; $e$, $a$, $b$ = length of lever arms, in., as shown in Fig. 20; $W$ = weight of motor, lb.; $P$ = load transmitted, Hp.; $k = 126{,}000/Nd$, in which $N$ = r.p.m. of motor, and $d$ = motor pulley diameter, in.

The maximum theoretical load that can be transmitted is $P = eW/ak$. In practice, the maximum load that can be transmitted is limited by slip of the belt, and is about 75% of the theoretical maximum.

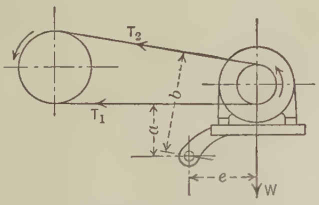

Fig. 20. Lever Arms in Pivoted Motor Drive

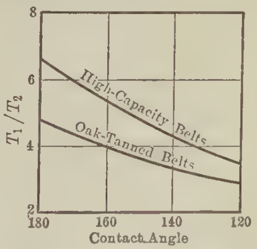

Fig. 21. Tension Ratio in Terms of Contact Angle with Paper Pulleys

In applying equations [17] to [19] to the design of a pivoted motor drive, the ratio of the tensions first is determined. High values of $T_1/T_2$ correspond to low values of $T_2$, with danger of excessive slippage. Low values of $T_1/T_2$ correspond to high total tension, with good frictional grip of the belt on the pulleys. Excessive values of $T_1/T_2$, however, tend to shorten belt life and burn out bearings. Fig. 21 gives values used by the author in connection with paper motor pulleys. Let $R$ = tension ratio selected; $W$ = weight of motor, lb.; $N$ = full speed of motor, r.p.m.; $P$ = maximum load to be transmitted, Hp., = rated Hp. × 1.5 for compensator start = rated Hp. × 2.5 for across line start; $D$, $d$, = respectively, diameter, in., of driven and motor pulleys; $r = d/2$;

$h$ = height of motor shaft above pivot; $k = 126{,}000/Nd$; $m$, $n$ = respectively, angle of slant of tight and slack strands of belt; $x$ = horizontal distance, motor shaft to driven shaft, in.; $y$ = height of driven shaft above motor shaft, in. $= -y$ if driven shaft is below motor shaft; $C$ = center distance between shafts, in. Then

$$R = T_1/T_2 = \{(eW/kP) + b\}/\{(eW/kP) - a\} \quad . \quad . \quad . \quad . \quad [20]$$

and

$$Ra + b = (R - 1)eW/kP \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [21]$$

Lengths of lever arms $a$, $b$ and $e$ are found by

$$a = h \cos m + e \sin m - r \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [22]$$

$$b = h \cos n + e \sin n + r \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [23]$$

In the equations [22] and [23], $r$ is positive when the tight strand is on the pivot side of the pulley and negative when the slack strand is on the pivot side.

By substituting equations [22] and [23] in equation [21] and solving for $e$, we have

$$e = \frac{h(R \cos m + \cos n) - (R - 1)r}{\{(R - 1)W/kP\} - R \sin m - \sin n} \quad . \quad . \quad . \quad . \quad . \quad . \quad [24]$$

In using equation [24], $r$ is positive when $T_1$ is on the pivot side of the pulley, and negative when $T_2$ is on the pivot side. $h$ is negative if the pivot is higher than the motor shaft, as in wall or ceiling mountings. Angles $m$ and $n$ are measured upward from a horizontal axis through the motor shaft drawn toward the pivot side. If either strand of the belt slopes downward from the motor, the corresponding angle, therefore, is negative. Angles $m$ and $n$ are computed as follows: Let $A$ = the half-angle between belt strands.

$$A = \sin^{-1} (D - d)/2C \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [25]$$

The angle of slope of the center line of shafts is $S$.

$$S = \tan^{-1} y/x = \sin^{-1} y/C \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [26]$$

$S$ is negative when $y$ is negative. Then

$$m = S - A \text{ when } T_1 \text{ is on pivot side of pulley.}$$
$$= S + A \text{ when } T_2 \text{ is on pivot side of pulley.}$$
$$n = S + A \text{ when } T_1 \text{ is on pivot side of pulley.}$$
$$= S - A \text{ when } T_2 \text{ is on pivot side of pulley.}$$

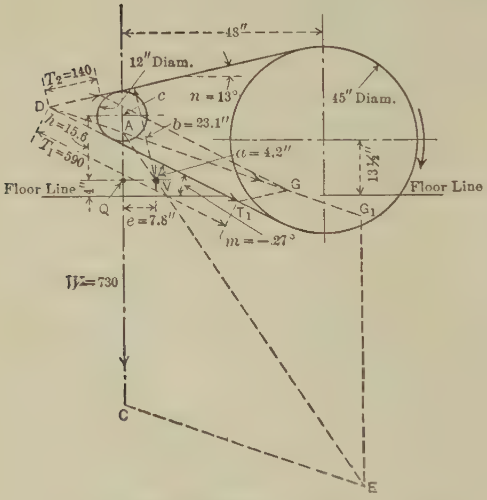

FIG. 22. Graphical Method of Laying Out Pivoted Motor Drive

EXAMPLE.—See Fig. 22. Determine the pivot distance for a drive using a high-capacity belt on a paper motor pulley, under the following conditions: Motor, 25 Hp., compensator started, whence $P = 25 \times 1.5 = 37.5$; r.p.m. $= 865 = N$; weight of motor, 730 lb. $= W$; diameter of motor pulley, 12 in. $= d$; distance of motor shaft above feet = 11 in.; distance of pivot below top surface of pivoted base arms = $4\,^9/_{16}$ in., whence $h = 11 + 4\,^9/_{16}$ in. $= 15.6$; $r = +6$ (positive, because $T_1$ is on pivot side of pulley); diameter of driven pulley, 45 in. $= D$; center line distance $= 48.3 = C$. *Solution.*—Value of $k$ is found from

$$k = 126{,}000/Nd$$
$$= 126{,}000/(865 \times 12) = 12;$$

$kP = 450$, and $WkP = 1.62$. From equation [25] $A = \sin^{-1} (45–12)/96.6 = 20$ deg. From Fig. 21, $R = 4.3$. Angles $m$ and $n$ are found by computation, or by measuring with a protractor to be $m = -27$ deg., $n = 13$ deg., whence $\cos m = 0.891$, $\sin m = -0.454$; $\cos n = 0.974$, $\sin n = 0.225$. From equation [24]

$$e = \frac{15.6\{4.3(0.891) + 0.974\} - (4.3 - 1)6}{(4.3 - 1)1.62 - 4.3(-0.454) - 0.225} = 7.83 \text{ in.}$$

The tension ratio will be 4.3 at a peak load of 37 ½ Hp. if the pivot is 7.83 in. back of the motor shaft.

**Graphical Method.**—See Fig. 22. Draw to scale the motor pulley and the driven pulley in their respective locations. Calculate the two tensions from $T_1 - T_2 = kP$ and

$T_1/T_2 = R$, whence $T_2 = kP/(R-1)$, and $T_1 = RT_2$. Lay off to scale the tensions $T_1$ and $T_2$ from their point of intersection $D$. Construct the parallelogram of forces, and draw the resultant $DG$. Draw the vertical center line of the motor pulley, making $cC$ equal to the weight of the motor, to the same scale as used for the tensions. Prolong $DG$ to $G_1$, making $AG_1 = DG$. On $AG_1$ draw the parallelogram $AG_1EC$, and draw the diagonal $AE$. On $cC$ locate point $Q$, making $cQ$ equal to the distance $h$ of the center line of the motor above the pivot. This distance $h$ is fixed by the dimensions of the motor and the pivoted base. Through $Q$ draw a horizontal line intersecting $AE$ at $V$, which is the location of the pivot, and which can be scaled from the drawing.

## 7. BELT DATA

**U. S. NAVY DEPARTMENT SPECIFICATIONS FOR BELTING.**—Belts shall be made from No. 1 native packer steer hides or their equal. They shall be tanned with white or chestnut oak by the slow process for six or eight months; chemical processes are not permitted. The leather is to be thoroughly curried by hand and must not be stuffed or loaded for artificial weight. The leather must not crack open on the grain side when doubled strongly by hand with the grain side out. All belting shall be cut from the central part of the hide, not more than 15 in. from the backbone or more than 48 in. from the tail toward the shoulder. Belts 8 in. wide and over must be cut to include the backbone. All leather must be stretched 6 in. in the lengthwise direction and should not exceed 54 in. after stretching. Centers and sides are to be stretched 6 in. separately. That is, all sides from which widths of less than 8 in. are cut must be stretched after the backbone section has been removed. Center sections are to be stretched in the same size for which they are to be used.

For single belts up to 6 in. wide the laps must not exceed 6 in. nor be less than 3 1/2 in. long. For single belts wider than 6 in., the laps should not be more than 1 in. longer than the width of the belt. For double belts, laps must not be more than 5 1/2 in. nor less than 3 1/2 in. long. Filling straps are not permitted. All laps must be held securely at every point with the best quality of belt cement, and when pulled apart must not show any resinous, oily, vitreous or watery condition. The belts should be again stretched after manufacture.

**Weight.**—Single belts, all sizes, 16 oz. per square foot; double belts: 1 to 2 in. wide, 26 oz. per sq. ft.; 2 1/2 to 4 in. wide, 28 oz. per sq. ft.; 4 1/2 to 5 1/2 in. wide, 30 oz. per sq. ft.; 6 in. wide and over 32 oz. per sq. ft.

**Rawhide Lacing.**—Only hand-cut green slaughter-house hides are to be used for lacing. They are to be cut in the following sizes: 1/4, 5/16, 3/8, 7/16, 1/2, 5/8 and 3/4 in. They must be cut lengthwise from the hide and have a tensile strength of not less than

| Width, in. | 1/4 | 5/16 | 3/8 | 7/16 | 1/2 | 5/8 | 3/4 |
|---|---|---|---|---|---|---|---|
| Tensile strength, lb. per sq. in. | 95 | 125 | 155 | 165 | 180 | 205 | 230 |

**LENGTH OF BELTS.**—Whenever possible, the length of belt required for a pair of pulleys should be determined by actual measurement by means of a steel tape passed around the pulleys. Where this is impracticable, the length of an open belt can be determined by calculation, using one of the three following formulas (Carl G. Barth, *Am. Mach.*, Mar. 12, 1903):

$$L = \frac{(D+d)\pi}{2} + Cx + 2C \qquad [27]$$

$$L = \frac{(D+d)\pi}{2} + Cx\frac{12}{12-x} + 2C \qquad [28]$$

$$L = \frac{(D+d)\pi}{2} + Cx\frac{60-13x}{60-18x} + 2C \qquad [29]$$

where $L$ = length of belt; $D$ = diam. of larger pulley and $d$ = diam. of smaller pulley; $C$ = center to center distance of pulleys, all in the same unit, in. or ft., $\pi = 3.1416$, and $x = \{(D-d)/2C\}^2$. The accuracy of the formulas is as follows, testing them by the limiting case where $d = 0$ and $C = D/2$, giving $L = D\pi$: Formula [27] gives a result somewhat over 2% short; formula [28] gives a result about 1% short; formula [29] gives a result under 0.4% short.

**Crossed Belts.**—Using above notation, length of crossed belts is given exactly by

$$L = \frac{(D+d)\pi}{2} + (D+d)\frac{\pi\beta}{180} + 2L\cos\beta; \quad \beta = \sin^{-1}\frac{D+d}{2L} \qquad [30]$$

**LENGTH AND WEIGHT OF BELTING.**—The length of a belt when closely rolled may be found as follows: Let $D$ = diameter of roll, in., $d$ = diameter of eye, in.,

$N$ = number of coils in roll, $L$ = length of belt, feet. Then $L = 0.1309\ (D + d)N$.

**Approximate Weight of Belts.**—Let $L$ = length of belt, ft., $w$ = width of belt, in., $C$ = a constant = 13 for single, and 8 for double belts. Then, weight of belt, $W$, lb., is $W = L \times w/C$.

**THICKNESS OF LEATHER BELTING.**—Specifications of the American Leather Belting Assoc. give the thickness of first quality leather belting as follows:

| Medium Single | Heavy Single | Light Double | Medium Double | Heavy Double |
|---|---|---|---|---|
| $^{10}/_{64}$–$^{12}/_{64}$ in. | $^{12}/_{64}$–$^{14}/_{64}$ in. | $^{15}/_{64}$–$^{17}/_{64}$ in. | $^{18}/_{64}$–$^{20}/_{64}$ in. | $^{21}/_{64}$–$^{23}/_{64}$ in. |

The thicknesses are average thicknesses in inches, determined by measuring 20 coils and dividing this value by the number of coils measured. In rolls of belting containing less than 20 coils, average thickness should be determined by measuring one-half the total number of coils and dividing this value by the number of coils measured. No point in either single or double belting shall be more than $^2/_{64}$ in. thicker or thinner than the average thickness.

**STRENGTH OF BELTING.**—The ultimate tensile strength of belting does not generally enter as a factor in calculations of power transmission. The strength of the solid leather in belts is from 2000 to 5000 lb. per sq. in.; at the lacings, even if well put together, only about 1000 to 1500. If riveted, the joint should have half the strength of the solid belt. The working strain on the driving side generally is taken at not over one-third of the strength of the lacing, or from one-eighth to one-sixteenth of the strength of the solid belt.

**SAG OF BELTS. DISTANCE BETWEEN PULLEYS.**—Shafts that are to be connected with belts should be at such distance as to allow of a gentle sag to the belt when in motion. A general rule is: Where narrow belts are to be run over small pulleys, 15 ft. is a good average, the belt having a sag of 1 $^1/_2$ to 2 in. For larger belts, working on larger pulleys, the distance should be 20 to 25 ft., with a sag of 2 $^1/_2$ to 4 in. For main belts working on very large pulleys, the distance should be 25 to 30 ft., with a sag of 4 to 5 in. If too great a distance is attempted, the belt will have an unsteady flapping motion, which will destroy both the belt and machinery.

**EFFECT OF HUMIDITY UPON A LEATHER BELT.** (W. W. Bird and F. W. Roys, *Trans.* A.S.M.E., 1915.) Tests with a 4-in. oak-tanned single belt, with constant horsepower transmitted, and with the center distance and humidity varying, showed increase of the sum of the tensions as the humidity decreased. Figures taken from curves of the results are as follows:

| Center distance | 9 ft. 6 in. | 9 ft. 6 $^1/_2$ in. | 9 ft. 7 in. | 9 ft. 7 $^1/_2$ in. |
|---|---|---|---|---|
| Relative Humidity | | Sum of the Tensions, pounds | | |
| 90 | 95 | 210 | 325 | 445 |
| 55 | 125 | 260 | 400 | 550 |
| 20 | 150 | 310 | 465 | 620 |

Increase of temperature as well as increase of humidity tends to lengthen the belt and decrease the tension. The most important conclusions are:

1. If a belt be set up at a medium relative humidity, the tensions will not be excessive at lower relative humidities, nor will there be any great danger of slipping at high relative humidities unless there are excessive temperature changes.

2. If a belt be set up at any relative humidity with a spring or gravity tightener, a load 50% greater than the standard can be transmitted at either high or low humidity without danger of stretching the belt, slipping, or excessive pressure on the bearings.

**COEFFICIENT OF FRICTION.**—The coefficient of friction of a belt on a pulley varies with the character of the belt and with the type of surface and condition of surface of the pulley. It also varies with the velocity of the belt. (See p. 24–15.) Table 15 from

**Table 15.—Coefficient of Friction of Belts on Pulleys**

| Kind of Belt | Friction Surface of Pulley | | | | | | |
|---|---|---|---|---|---|---|---|
| | Iron | Steel | Wood | Paper | Wet Iron | Greasy Iron | Oily Iron |
| Oak-tanned leather | 0.25 | 0.25 | 0.30 | 0.35 | 0.20 | 0.15 | 0.12 |
| Mineral-tanned leather | .40 | .40 | .45 | .50 | .35 | .25 | .20 |

| Rubber on fabric | .35 | .35 | .38 | .40 | .20 | ........ | ........ |

*Machy.*, March 1931, gives the coefficient of friction of various types of belts on various pulley surfaces. These coefficients probably are average values and take no account of the variation due to velocity.

## 8. MISCELLANEOUS TYPES OF BELTS

**RUBBER BELTING.**—The advantages claimed for rubber belting are perfect uniformity in width and thickness; it will endure a great degree of heat and cold without injury; it is also specially adapted for use in damp or wet places, or where exposed to the action of steam; it is very durable, and has great tensile strength, and when adjusted for service it has the most perfect hold on the pulleys, hence is less liable to slip than leather.

*Never use animal oil or grease on rubber belts*, as it will soon destroy them.

Rubber belts will be improved, and their durability increased, by putting on with a painter's brush, and letting it dry, a composition made of equal parts of red lead, black lead, French yellow, and litharge, mixed with boiled linseed-oil and japan enough to make it dry quickly. The effect of this will be to produce a finely polished surface. If, from dust or other cause, the belt should slip, it should be lightly moistened on the pulley side with boiled linseed-oil. Table 16 gives the properties of rubber belting and the maximum tensions under which it should be operated.

**STITCHED CANVAS BELTING.**—The widths of stitched canvas belts vary with the thickness, ranging as follows: 4-ply, 1 1/2 to 18 in.; 3-ply, 3 to 30 in.; 8-ply, 40 to 48 in.; 10-ply, 12 to 60 in. Widths increase by 1/2 in. up to 5 in. wide, and by 1 in. up to 14 in. From 14 in. to 32 in. widths increase by 2 in. Above 32 in., canvas belts are made 36, 40, 48, 54 and 60 in. wide. Table 17 shows the properties of stitched canvas belting.

**TEON BELTING** is a cotton belt impregnated with a special composition to enable the belt to work effectively in heat, steam, water and chemically charged atmospheres under abnormal conditions. It is reinforced with a stitching of copper wire extending in rows lengthwise of the belt, which practically eliminates stretching, the stretch at 190 lb. per sq. in. of belt tension being 0.09 in. The belt is unaffected by temperature variation up to 250° F. Table 18 gives the horsepower capacity of these belts as stated by the maker.

Teon belting is made in the following widths: Light belt, 1, 1 1/4, 1 1/2, 2, 2 1/2, 3, 3 1/2, 4 in.; min. diam. of pulley, 3 in. Medium belt, 1 to 2 in., increasing by 1/4 in.

* Based on 180 deg. arc of contact on both pulleys. For other arcs of contact, the tabular values should be increased or decreased as follows: 210 deg., + 11%; 200 deg., + 7%; 190 deg., + 4%; 170 deg., −4%; 160 deg., −8%; 150 deg., −13%.

**BALATA BELTING** is canvas belting impregnated with balata gum, which makes it waterproof and resistant to animal oil. Mineral oils affect it adversely, as do temperatures above 120° F. Table 19 gives the properties of balata belting.

## CHAIN DRIVES

Power transmission chains may be broadly classified as roller chains, block chains, inverted-tooth or silent chains, and malleable chains. The latter are used principally in conveyor applications and for very slow speed drives. For the transmission of power at high chain velocities, the other types are preferred. Block chains comprise 8-shaped or B-shaped blocks with side links riveted to them at both ends. Block chains are used only for light transmissions and at speeds under 800 ft. per min.

### 1. ROLLER CHAINS

Roller chains have been standardized, and all manufacturers of this type of chain build their chains and sprockets in conformity with American Standard A.S.A.–B29a–1930. The following notes are abstracted from that standard. This standard is subject to periodic revision and the latest issue should be consulted.

**TYPES OF ROLLER CHAINS.**—A roller chain comprises a series of pin-links and roller-links assembled together. The roller-link consists of two plates, between which are inserted a pair of bushings, each carrying a steel roller. The pin-link consists of a pair of pins riveted to a side plate, the pins passing through the bushing of the adjacent roller link. They are held in place by a side plate fitting over the projecting ends of the pins.

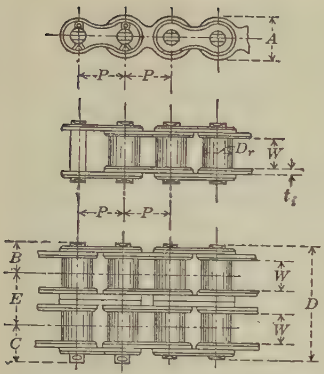

FIG. 1. Dimensions of Commercial Standard Roller Chain

The pins either are riveted over the side plate or are secured by cotters. The bushings are free to turn on the pins, and the rollers are free to turn on the bushings. The distance between the center lines of the pin-links and between the center lines of the bushings of the roller-links is equal to the pitch of the chain. The plates forming the tension members of a roller-link are known as inside plates, and the plates forming the tension members of the pin-link are known as pin-link plates.

Roller chains are made in the standard series, the extra heavy series, and light-weight machinery chain, and also in single, double, triple and quadruple width chain. The center plates in multiple width chains have a thickness equivalent to two thicknesses of inside plates as used on the roller links. Dimensions of commercial standard roller chain are given in Table 1. Light-weight machinery chain, designated as No. 41, is 1/2 in. pitch, 1/4 in. wide, and has side plates 0.050 in. thick. The pin diameter is 0.141 in., and the roller diameter is 0.306 in.

Dimensions of the standard and extra heavy series are given in Table 2. Extra heavy chains are similar in all dimensions to the standard chain, with the exception of the inside plates, which are thicker than the standard plates.

**PROPORTIONS OF CHAINS.**—Standard chains are made in the following pitches: 3/8 in., 1/2 in., 5/8 in., 3/4 in., 1 in., 1 1/4 in., 1 1/2 in., 1 3/4 in., 2 in.

If $P$ be the pitch of the chain, in., the proportions of standard chains are determined approximately as follows: Roller diameters, $5/8\ P$; width (minimum distance between inside plates) is the nearest binary fraction to $5/8\ P$; in the narrow series, width is the nearest binary fraction to $0.41\ P$. Pin diameters are approximately $5/16\ P$, or 1/2 of the roller diameter. Thickness of inside plates, standard series, is approximately $1/8\ P$.

Under exceptional conditions, values given by the above equations may be increased by as much as 25%, but only when lubrication and installation, as well as the design of the drive is correct. If lubrication is poor, or the chain is subject to suddenly applied loads or continuous service, or where unusually long life is required, or if the sprockets are subject to misalignment, chains should be selected on a basis of approximately one-half of the loads given by the equations. Tables 3 and 4 show the working loads and horsepowers transmitted by various chains on the basis of equations [2] and [3]. The tables are based on sprockets having not less than 15 teeth.

**CHAIN VELOCITY.**—A chain that is satisfactory in all other respects may prove impracticable due to its velocity being limited by the permissible velocity of the sprocket. The maximum allowable impact between chain rollers and sprocket teeth limits sprocket speed to

$$\text{r.p.m.} = (1920/P) \times \sqrt{A_r/W_f P} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \qquad [1]$$

where $P$ = pitch, in.; $A_r$ = projected area of roller, sq. in.; $W_f$ = weight of chain, lb. per ft. The maximum revolutions per min. of sprockets as calculated from this equation for standard roller chains are given in Tables 3 and 4. Maximum chain velocities are given in Table 5.

**Maximum Chain Velocity** $= 75\ n \div \sqrt{P}$, where $n$ is the number of teeth in the smaller sprocket. Under favorable conditions, the chain velocity can be very high but with

**Table 5.—Maximum Velocities of Standard Roller Chain**

unfavorable conditions, 400 ft. per min. may be too great. The critical velocity is reached with the sprocket at its maximum speed.

**STANDARD CHAIN NUMBERS.**—The right-hand digit of the chain number is zero for chains of the usual proportions, 1 for a light-weight chain, and 5 for a rollerless bushing chain. Digits to left of the right-hand digit denote the number of $^1/_8$ inches in the pitch.

The extra-heavy series is designated by the letter H following the chain number. Multiple-width chains are designated by prefixes to the chain number, as follows: D, double-width; E, triple-width; F, quadruple-width, etc.

**Tolerances.**—Chain length may be over-length $^1/_{64}$ in. per foot, but may not be under-length. Chain lengths shall be determined when subjected to a measuring load of $^1/_{32}$ of the test load (see below).

Maximum pin diameters = nominal pin diameter + 0.0005 in.

Minimum hole in bushing = 1.006 nominal pin diameter + 0.005 in.

Minimum clearance between pins and bushings = 0.006 nominal pin diameter.

Maximum width of roller link =

(nominal width of chain) + (2.05 × nominal side plate thickness) + $C$,

where $C$ = 0.005 in. for side plates up to and including 0.156 in. thick, and 0.007 in. for thicker side plates.

Minimum distance between pin plates = maximum width of roller link + 0.002 in.

**LOADS.**—**Test Load** is the load under which a chain should be tested for material defects. For single width chains

$$\text{Test load} = 42{,}000 \times (\text{pin diameter})^2 - 280 \text{ lb.}$$

**Working Load.**—Equation [2] given below is a guide for the selection of chains. Let $F$ = working load, lb.; $A_p$ = projected bearing area of pin, *i.e.* diameter of pin × length of bushing, both in inches; $V$ = chain velocity, ft. per min.; $W_f$ = weight of chain, lb. per ft. Then

$$F = 2{,}600{,}000\, A_p/(V + 600) \qquad [2]$$

When the chain velocity exceeds 800 ft. per min., the value of $F$, as found above, should be diminished by the quantity $W_f V^2/115{,}900$, which represents the centrifugal tension in the chain. The horsepower transmitted by the chain then will be

$$\text{Hp.} = FV/33{,}000 \qquad [3]$$

**LENGTH OF CHAIN.**—Let $P$ = pitch of chain, in.; $C$ = center to center distance of sprockets, pitches; $N$ = number of teeth in large sprocket, in.; $n$ = number of teeth in small sprocket, in.; $L$ = length of chain in pitches. Then

$$L = 2C + {}^1/_2\,(N + n) + \{0.0257\,(N - n)^2/C\} \qquad [4]$$

As a chain cannot contain a fractional part of a pitch, the next whole number above the calculated number of pitches must be used. If it is an odd number, an offset link should be used. The chain length in inches = $L \times P$.

If the center to center distance can be adjusted to suit the length of the chain, an even number of pitches should be chosen to avoid using an offset link. The proper center to center distance then may be found by the equation

$$C' = {}^1/_8\, P\{2L - N - n + \sqrt{(2L - N - n)^2 - 0.824\,(N - n)^2}\}, \qquad [5]$$

where $C'$ = center to center distance of sprockets, in. $C'$ should not be less than 12 $P$ nor less than the pitch diameter of the large sprocket. If possible, adjustment for the center to center distance should be provided to take up excessive slack in the chain due to elongation from wear. A slack in the chain of, say, $^1/_4$ to $^1/_2$ in. drop per foot of span should always be allowed.

**SELECTION OF PROPER CHAIN AND SPROCKETS.**—From the known data, such as horsepower, r.p.m., and center to center distance, the other data can be found from the tables and equations for chain pull, chain velocity, etc., for a trial drive. Select the shortest pitch chain that will carry the load, giving preference to the standard chains. Assume the number of teeth to be used in the sprockets; calculate the chain pull $F$ and the chain velocity $V$, and examine the tables and rules to determine if everything is within safe limits; make the necessary change in chain or sprockets, and again apply the test.

**BEST CONDITIONS OF DRIVING.**—The highest efficiency is reached in a chain drive when the center to center distance can be so adjusted that there will be an integral number of pitches between the points of tangency of the chain on the pitch circles of the two sprockets. Under this condition, the angular velocity ratio between sprockets is most nearly uniform. The true pitch line of a sprocket is a polygon of as many sides as there are sprocket teeth. During the passage of each tooth, the distance of the center line of the chain from the center of the sprocket varies. If one end of the tight strand rises while the other end falls and *vice versa*, there is a tendency to produce rapid fluctuations in the angular velocity ratio between the sprockets. The smoothest action is obtained when the two ends rise and fall in unison. The larger the number of teeth in the sprocket the closer will the polygon approach a circle. This explains why sprockets with few teeth are undesirable unless the motion is so slow that the inertia of the driven wheel and its accessories has but little effect.

Where the center to center distance is not too short, the slack strand may be either above or below. For short centers it is better to have it below. Chains may be run at any angle, but they run best when nearly horizontal. Many successful vertical drives have been installed. In such cases, the slack must not be allowed to develop to a point where the chain may jump the teeth on the lower wheel.

Idler or "jockey" sprockets should be avoided if possible. If, however, it is necessary to use them, they should be as large as possible and as well-made and well-mounted as the main sprocket. A little side float on the idler pin is desirable. Idlers never should be placed against the tight strand, nor should they ever be run above the maximum speed allowed for regular driving sprockets.

When the chain elongates to $3/8$ in. per foot it should be replaced. If any part of a link needs repair the whole link should be replaced. Excessive slack with non-adjustable centers may be corrected by removing two links and inserting an offset link, thus shortening the chain by one pitch.

Sometimes the load may be divided between two single roller chains, the sprockets running side by side. In this case, the teeth of the two parallel sprockets should be opposite and not staggered. Also the two chains should be of equal length with the roller links of one opposite the roller links of the other. If removed, each chain should be replaced over exactly the same teeth as before.

Maximum service and minimum wear of sprockets and chains are obtained when the sprockets are aligned with their mid-planes coincident.

The general conditions affecting the efficiency of a chain drive are as follows: 1. Increasing the number of teeth in the sprocket. 2. Decreasing the velocity ratio represented by r.p.m. of driver ÷ r.p.m. of driven wheel. 3. Increasing the load. 4. Continuous lubrication in an oil bath. 5. Making the center to center distance such that the span of chain on the tight side is an exact multiple of the pitch. 6. Reducing the r.p.m. 7. Decreasing the pin diameter. 8. Decreasing the diameter of the sprocket bearing. 9. Shortening the pitch. 10. Reducing the weight of the chain.

**SPROCKET PROPORTIONS.**—The pitch diameter of a sprocket is given by

$$D_p = P/\sin\,(180\ \text{deg.}/T) \qquad [6]$$

where $D_p$ = pitch diam., in.; $P$ = pitch of chain, in.; $T$ = number of teeth. Dimensions of the section profile (see Fig. 2) are given by the following equations, in which $t$ = thickness of sprocket, in.; $t_p$ = thickness of inside plate, in.; $h$ = depth of chamfer, in.; $g$ = width of chamfer, in.; $r$ = radius of chamfer, in.; $Q$ = depth of shroud, in.; $W$ = width of chain, in.; $K$ = transverse pitch of multiple width sprockets, in.;

$$\text{For single-width chain, } t = 0.93\,W - 0.006 \qquad [7]$$

$$\text{For double- and triple-width chain, } t = 0.90\,W - 0.006 \qquad [8]$$

$$\text{For quadruple-width chain and over, } t = 0.88\,W - 0.006 \qquad [9]$$

$$h = 0.5\,P \qquad [10]; \qquad r = 1.063\,P \qquad [11]$$

$$g = 0.125\,P \qquad [12]; \qquad Q = 0.5\,P \qquad [13]$$

$$K = W + 4.15\,t_p + 0.003 \qquad [14]$$

Minimum outside diameter of sprocket is

$$D_o = P[0.6 + \{\cot\,(180\ \text{deg.}/T)\}] \qquad [15]$$

$$\text{Bottom diameter of sprocket} = D_p - \text{roller diameter.}$$

$$\text{Maximum hub diameter} = D_p - P.$$

Dimensions of commercial sprockets are given in Tables 6 and 7.

**Tolerances.**—The tolerances on the bottom diameter of cut sprockets is $+\ 0.000$ in., $-\ (0.003\text{ in.} + 0.001\,P\sqrt{T})$. Tolerance on sprocket thickness is $\pm\ W/50 + 0.002$ in.

The advantages of standard tooth forms are: (*a*) Distribution of the load among several teeth; (*b*) elimination of jerks when the links come into and pass out of action; (*c*) means to provide for chain elongation by allowing the successive rollers to climb the teeth and adapt themselves to their natural pitch line; (*d*) Quieter action resulting in greater efficiency and longer life; (*l*) Less tendency of the teeth to wear hook-shaped.

The rollers of a new chain of correct pitch will seat themselves at the bottom of the tooth spaces. After the chain has elongated, one roller only at any particular instant will be seated at the bottom of the tooth space. From that point the successive rollers will

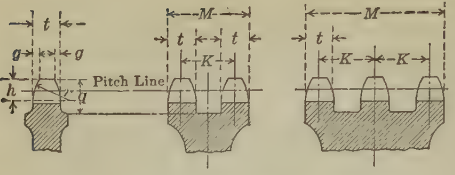

FIG. 2. Transverse Sprocket Tooth Profiles

take higher positions on the working face of the tooth until they have reached a pitch circle large enough to accommodate the increased pitch of the chain. The greatest pressure is on the first tooth, with continually lessened pressure on each successive tooth until the last or "bedding" roller is reached.

If the speed of the smaller wheel is over 60% of the maximum r.p.m. as given in Tables 3 and 4, the sprockets should be widened and all sharp burrs on the edges of the teeth removed. Smaller running sprockets may be made of machine steel, cast iron, semi-steel or bronze.

### Table 6.—Sprocket Tooth Dimensions for Roller Chain

(Morse Chain Co., Ithaca, N. Y.)

| Chain No. | Pitch $P$, in. | Nominal Roller Diam., $D_r$, in. | Sprocket Tooth Dimensions, in. (See Fig. 2) | | | | | | | | | | |

| 35 | 11.1558 | 11.711 | 65 | 20.6982 | 21.274 | 95 | 30.2446 | 30.828 | 125 | 39.794 | 40.381 |

**NUMBER OF TEETH.**—The number of teeth in the sprockets should not be less than 14, unless the speed is very low. However, when a sprocket runs at a low speed, 8, 7 or even 6 teeth may be used if it is not practicable to use a higher number. At moderately high speeds, such low numbers of teeth are inefficient and destructive to the chain.

Whether the number of teeth should be odd or even is a disputed question. If a chain, after cleaning or repairs, is replaced so that the same links mesh with the same teeth as before and further, if there is an even number of pitches in the chain, *i.e.*, no offset links, an even number of teeth is advantageous. In that case one-half of the teeth will so wear as to work best with inside links which do not elongate from wear; the other half will accommodate themselves to the increasing length of the pin links. Otherwise an odd number of teeth is preferable, as then every tooth will mesh alternately with both kinds of links in the chain.

**CUTTERS FOR SPROCKET TEETH.**—Three types of cutters are used for cutting sprocket teeth, *viz.*: Convex cutters, straddle cutters and hobs. Convex cutters will cut the following ranges of teeth: 7–8, 9–11; 12–17; 18–34; 35 and over. These cutters are of the common type, designed to cut the spaces between the teeth. Straddle cutters are designed to straddle the teeth and cut a part of two spaces at the same time. Two straddle cutters will fill the requirements for all numbers of teeth. Hobs are made to cut any required number of teeth of a given pitch and roller diameter. Proportions of cutters are given in American Standard A.S.A. B29a–1930, together with proportions of pattern teeth for cast sprockets.

## 2. SILENT CHAINS

A "silent" or high-speed chain consists of a series of leaves of the shape shown in Fig. 3, which are assembled by means of pins and bushings to form various widths of chain, as shown in Fig. 4. The chain engages with the sprocket as shown in Fig. 5. As the pitch lengthens, due to wear, the links adjust themselves to a larger pitch circle as shown in Fig. 4, thus automatically compensating for wear. These chains can be run in either direction at velocities up to 1500 ft. per min. without noise or shock.

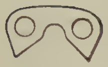

FIG. 3

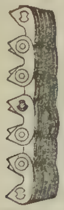

FIG. 4

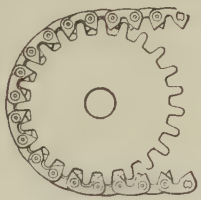

FIG. 5

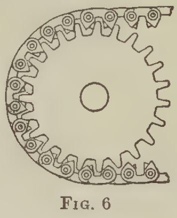

FIG. 6

Silent Chain

**ALLOWABLE TENSION.**—The values of normal tension given in Table 8 may be increased when the speed of the chain is low, and must be decreased with high speeds. The following figures show the percentage variation from normal tension with variation in speed:

| | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Percent of normal r.p.m.. | 10 | 20 | 30 | 40 | 50 | 60 | 70 | 80 | 90 | 100 | 110 | 120 | 130 | 140 | 150 |
| Percent of normal tension | 300 | 300 | 235 | 200 | 165 | 140 | 125 | 115 | 105 | 100 | 85 | 68 | 54 | 40 | 25 |

EXAMPLE.—Required the safe tension on a 1-in. pitch chain, 3 in. wide, at 1200 r.p.m. and at 600 r.p.m. From Table 2, the normal tension is 3 × 205 = 615 lb. at 1000 r.p.m. At 1200 r.p.m., the speed is 1200/1000 = 120% of normal. Hence the permissible tension is 0.68 × 615 = 417.5 lb. At 600 r.p.m., the speed is 600/1000 = 60% of normal, and the allowable tension is 1.40 × 615 lb. = 861 lb.

Other factors which tend to reduce the allowable tension are continuous operation (24 hr. per day), reversing service, drives subject to shock, and drives in which the drive sprocket has less than 25 teeth. Manufacturers of silent chain should be consulted concerning drives involving unusual conditions.

**Length of Chain.**—If $P$ = pitch of chain, in., $T$ = number of teeth on larger sprocket, $t$ = number of teeth on smaller sprocket, $D$ and $d$ = pitch diameters of larger and smaller sprockets, in., respectively; $C$ = center to center distance between the sprockets, in., and $L$ = length of chain, and $\beta$ = angle whose sine is $\{{}^1/_2(D - d)/C\}$,

$$L = TP\{(180 + 2\,\beta)/360\} + tP\{(180 - 2\,\beta)/360\} + 2\,C\cos\beta\,. \quad . \quad . \quad [16]$$

**DESIGN OF CHAIN DRIVES.**—Pitch of chain first should be selected, on the basis of the values given in Table 8. The higher shaft speed is the limiting factor, and indicates

### Table 8.—Silent Chain Drive Data

| 1.5 | 8 | 1.184 | 1.038 | .878 | .878 | .848 | .122 |
| 2 | 6 | 1.227 | 1.037 | .837 | .837 | .807 | .163 |
| 3 | 3† | 1.250 | 1.000 | .674 | .674 | .644 | .163 |

* For each inch or half-inch increase in width of chain, add the increased width to dimensions given above. The first inch in width lacks one link. For example, 5/8 in. pitch, 1 in. wide = 11 links, 5 and 6 in alternate sections. For each additional inch or fraction, add as per second column of table. † Double.

the largest pitch chain that can be used. In general, the largest pitch gives the best drive, but limitations of sprocket diameters and necessity for quiet operation often dictate smaller pitches. For the most noiseless drive, the smallest pitch that will carry the load should be chosen. Large pitch chain should be used for slow speeds and large power.

**The Speed Ratio** is the basis of selection of driving and driven sprockets. The smaller sprocket usually is selected first, on the following basis:

| | | | |
|---|---|---|---|
| Speed ratio .......... | 3 : 1 to 5 : 1 | 5 : 1 to 6 : 1 | Over 6 : 1* |
| No. of teeth in pinion..... | 17, 19, 21 | 17 | 15 |

**Chain Speed** is determined by the equation

$$V = T \times \text{r.p.m.}/N \qquad [17]$$

where $V$ = chain velocity, ft. per min.; $T$ = number of teeth in sprocket; $N$ = number of links per foot of chain.

**Chain Width** is determined by first finding the total pull in the chain necessary to transmit the desired horsepower, and then ascertaining the width by means of the allowable tension for the chain used.

$$P = \text{Hp.} \times 33{,}000/V \qquad [18]$$

$$w = P/p \qquad [19]$$

where $P$ = total pull on chain, lb.; $p$ = pull on chain, lb. per inch of width (see Table 8);

---

* For chain pitches 1.2 in. and over, 17 teeth is the minimum. The number of teeth in the large sprocket should not exceed 130, and better results follow from a smaller number of teeth, especially with the smaller pitch chains. An odd number of teeth in both sprockets is advisable. If the speed ratio demands an even number, a hunting link should be used in the chain.

$V$ = chain velocity, ft. per min. The next greater width, in even inches or half-inches, as shown by Table 9, should be used.

**HORSEPOWER TRANSMITTED BY SILENT CHAINS** is given in Table 10.

**SILENT CHAIN SPROCKETS.**—Table 11 gives the weights of solid pinions and armed sprockets for silent chain. Hub lengths are given in Tables 12 and 13. Odd

* 2 Strands.

widths of chain take the hub projection for the next higher width. For cast sprockets the values in Table 11 are the length of hub on each side of the sprocket. Split sprockets should have longer hubs than solid sprockets. Spring sprockets should be used with pulsating loads, as an air compressor, and shearing pin sprockets for drives subject to shock.

**Table 11.—Weight per Inch of Face of Silent Chain Sprockets**

# ROPE DRIVING

## 1. MANILA AND COTTON ROPE DRIVES

**SYSTEMS OF ROPE DRIVING.**—Two systems of rope driving are in use: 1. The American or continuous system, Fig. 1, in which a single rope passes over the sheaves several times, the slack being taken up by a tension carriage, which also transfers the rope from the outside groove of the driven sheave to the opposite outside groove of the driving sheave. 2. The English multiple system, comprising one or more separate ropes alongside of each other in the pulley sheaves.

**The Continuous System** is adapted to drives where the shafts are not parallel, to vertical drives and to drives where the rope is exposed to the weather. A disadvantage, however, is that the breakage of a single strand puts the entire drive out of service.

The arrangement of the tension carriage is important. The slack preferably should

**Table 13.—Standard Hub Lengths for Cast-iron Silent Chain Sprockets**

be taken up on the slack side of the drive at the driving sheave. See Fig. 1. If this is not possible, it may be taken up at the driven sheave. See Fig. 2. The outside groove of the driven sheave then should be a loose sheave, and the rope led to it from the tension sheave, whence it is returned to the opposite outside groove on the driving sheave. The weight applied to the tension carriage should be just sufficient to prevent any tendency to slip in the rope. It can be approximated from the value of the tension in the slack side, as calculated by formula [4].

The number of grooves and length of rope that one tension carriage will serve varies with the conditions of the drive. It is advisable to limit the length of the rope in continuous drives of large power, and use two or more ropes, each served by a separate tension carriage. The American Mfg. Co. recommends that not over 10 or 12 laps of rope be allotted to a single tension sheave, and for long drives and those requiring heavy ropes the number of laps per tension carriage should be reduced in proportion to the length and weight of rope between driving and driven sheaves. The maximum length of rope served by one tension carriage should not exceed 3000 ft. under ordinary conditions, and the travel of the carriage should be at least 2% of the length of the rope, except for very long or very short ropes. Table 1 gives data which are useful in the design of rope drives.

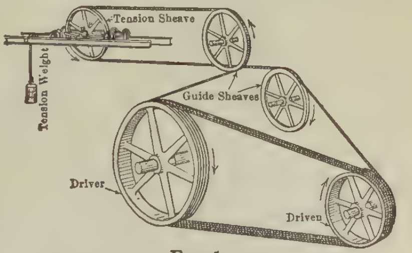

Fig. 1

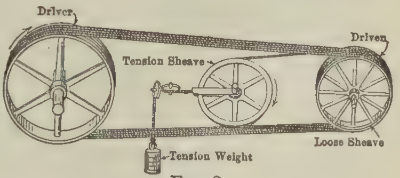

Fig. 2
Continuous Rope Drives

**The English Multiple System**, using separate parallel ropes, has no tension carriage, but depends on the weight of the ropes to provide the necessary tension. The power transmitted by a given drive may be increased at any time by the installation of additional ropes. An advantage of this system is that the breakage of a single rope does not put the drive out of service. Disadvantages are the difficulty of maintaining uniform

**Table 1.—Data of Manila Transmission Rope**

(American Mfg. Co., Brooklyn, N. Y.)

| Diam. of Rope, in. | Diameter² | Approximate Weight, lb. per ft. | Breaking Strength, lb. | Maximum Allowable Tension | Length of Splice, ft. | | | Smallest Sheave Diam., in. | Maximum r.p.m. |

| 1 3/8 | 1.8906 | 0.68 | 13,200 | 378 | 8 | 12 | 16 | 50 | 415 |
| 1 1/2 | 2.25 | 0.80 | 15,700 | 450 | 8 | 12 | 18 | 54 | 380 |
| 1 5/8 | 2.6406 | 0.92 | 18,500 | 528 | 8 | 12 | 18 | 60 | 344 |
| 1 3/4 | 3.0625 | 1.08 | 21,400 | 612 | 8 | 12 | 18 | 64 | 330 |
| 2 | 4. | 1.40 | 28,000 | 800 | 9 | 14 | 20 | 72 | 290 |
| 2 1/4 | 5.0625 | 1.80 | 35,400 | 1012 | 9 | 14 | 20 | 82 | 255 |
| 2 1/2 | 6.25 | 2.20 | 43,700 | 1250 | 10 | 16 | 22 | 90 | 230 |

Weight of transmission rope = 0.34 × diam.².
Breaking strength = 7000 × diam.².
Maximum allowable tension = 200 × diam.².
Diameter of smallest practicable sheave = 36 × diam.
Velocity of rope (assumed) = 5400 ft. per min.

tension on the several ropes, with resultant excessive wear on the more heavily loaded ones; the necessity of protecting the drive from the weather; the inability to use it for vertical drives; and the requirement that the distance between sheaves must be sufficiently long to give the necessary tension on the ropes.

**EFFICIENCY OF ROPE DRIVES.**—(E. H. Ahara, *Trans.* A.S.M.E., xxxv, p. 557, 1913.)—The efficiency of rope drives decreases slightly with increasing speeds. It is not affected by variation of center to center distances from 25 to 150 ft. The following figures were obtained in tests of both multiple and continuous drives at 3/4 load with a constant rope speed of 4500 ft. per min., using 1-in. manila rope with a center to center distance of pulleys of 100 ft.:

| No. of ropes in drive | | 1 | 2 | 3 | 4 | 6 | 8 |
|---|---|---|---|---|---|---|---|
| Continuous drive efficiency | Open | 91 | 93 | 94 | 94 | 94 | 94 |
| | Up and over | 58 | 72 | 79 | 80 | 80 | 81 |
| Multiple drive efficiency | Open | 73 | 80 | 84 | 86 | 86 | 86 |
| | Up and over | 56 | 67 | 71 | 72 | 75 | 77 |

The continuous drive had 60-deg. grooves, and the multiple drive 45-deg. grooves. In the open drive, the ropes ran horizontally between two sheaves. In the up and over drive the rope was led upward from the driving sheave, horizontally over two idlers, downward and around the driven sheave, upward and horizontally over two idlers, and thence downward to the driving sheave.

**HORSEPOWER OF ROPE DRIVES.**—Let $T$ = working tension in rope, lb.; $T_1$ and $T_2$ = the total tension in tight and slack sides of rope, respectively; $t_1$ and $t_2$ = effective tension in tight and slack sides of rope, respectively, lb.; $t_c$ = tension due to centrifugal force; $V$ and $v$ = velocity of rope, ft. per min. and ft. per sec., respectively; $w$ = weight of rope per ft., lb.; $d$ = diameter of rope, in.; $S$ = breaking strength of rope, lb. Then

$$T = (t_1 - t_2), \qquad [1]$$

$$t_c = wv^2/g = wv^2/32.2, \qquad [2]$$

$$\text{Hp.} = TV/33{,}000 \qquad [3]$$

Tension $t_1$ may be considered as made up of: (1) tension doing useful work; (2) tension to balance the tension necessary for adhesion; (3) tension due to centrifugal force. Tension $t_2$ may be considered as made up of: (1) tension necessary for adhesion $T_a$; (2) tension due to centrifugal force, $t_c$.

Tension on the tight side is assumed to be double that on the slack side. Then $T_a/T = 1/2$, and $T_a = 1/2\ T$. Since $T_a = t_2 - t_c$, $t_2 = t_c + 1/2\ T$, and

$$T = t_1 - t_c - 1/2\ T, \qquad [4]$$

from which

$$T = 2/3(t_1 - t_c) \qquad [5]$$

Substituting the value of $T$ from [5] in equation [3],

$$\text{Hp.} = 2/3(t_1 - t_c)V/33{,}000 \qquad [6]$$

According to the American Mfg. Co., $t_1$ should be limited to $1/35\ S$, and $S$ may be taken

**Table 2.—Horsepower Transmitted by Single Manila Ropes**

(American Mfg. Co., Brooklyn, N. Y.)

| Diameter of Rope, in. | Velocity, feet per minute | | | | | | | | | | |

**Table 3.—Sag of Ropes in Rope Drives**

| Distance Between Pulleys, ft. | Sag on Driving Side, All Speeds, ft. | Sag on Slack Side | | | | |
|---|---|---|---|---|---|---|
| | | Velocity, feet per minute | | | | |
| | | 3000 | 4000 | 4500 | 5000 | 5500 |
| 30 | 0.19 | 0.45 | 0.39 | 0.36 | 0.33 | 0.30 |
| 40 | .34 | .80 | .69 | .64 | .59 | .53 |
| 50 | .53 | 1.2 | 1.1 | 1.0 | .92 | .84 |
| 60 | .76 | 1.8 | 1.7 | 1.4 | 1.3 | 1.2 |
| 70 | 1.0 | 2.4 | 2.1 | 1.9 | 1.7 | 1.6 |
| 80 | 1.4 | 3.2 | 2.9 | 2.5 | 2.3 | 2.1 |
| 90 | 1.7 | 4.0 | 3.5 | 3.2 | 3.0 | 2.7 |
| 100 | 2.1 | 5.0 | 4.3 | 4.0 | 3.7 | 3.3 |
| 120 | 3.0 | 7.2 | 6.2 | 5.7 | 5.3 | 4.8 |
| 140 | 4.1 | 9.9 | 8.5 | 7.8 | 7.2 | 6.6 |
| 160 | 5.4 | 12.9 | 11.1 | 10.2 | 9.5 | 8.6 |

as 7000 $d^2$; whence, $t_1 = 200\ d^2$. Substituting the values $t_1 = 200\ d^2$, and $t_c = wv^2/32.2$ in [6], we have

$$\text{Hp.} = {}^2\!/_3\ V\{200\ d^2 - (wv^2/32.2)\} \div 33{,}000$$

$$= 0.000\,022\,2\ V\{200\ d^2 - (wv^2/32.2\} \quad \ldots\ldots \quad [7]$$

Table 2 gives the horsepower that will be transmitted by single ropes at various velocities. It is based on a coefficient of friction of 0.31, corresponding to a groove angle of 45° and an arc of contact of 165°. (For theoretical discussion of the effect of arc of contact and coefficient of friction on the transmission of power by belts, bands, ropes, etc., see Belting, p. 24–14.)

Since the value of $T_c$ increases with the velocity of the rope, it is obvious that there is a certain speed at which the maximum horsepower will be transmitted. For a tension in the tight side of 200 lb. per sq. in. this is in the neighborhood of 80 ft. per sec. as shown by Fig. 3.

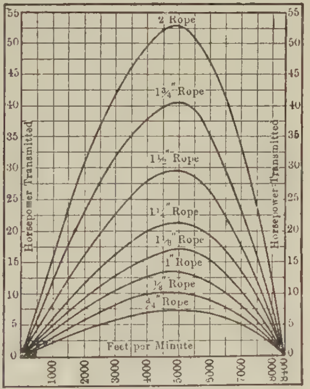

FIG. 3. Horsepower Transmitted by Manila Rope

**Sag of Rope.**—The catenary of the driving side is not affected by the speed or by the diameter of the rope. The deflection of the rope between the pulleys on the slack side varies with each change of load or speed. The deflections $D$ and $D_1$, or sag in the tight and slack sides, respectively, for horizontal drives may be approximated from equations [8] and [9], $t_1$ being taken as $200\,d^2$, and $L$ being distance between sheaves, ft.:

$$D = (wL^2)/8\,t_1 \quad \ldots\ldots \quad [8]; \qquad D_1 = (wL^2)/8\,t_2 \quad \ldots\ldots \quad [9]$$

The value of $t_2$ is found from equations [4] and [5]. Equations [8] and [9] will closely approximate the sag on the driving side for both multiple and continuous systems, and also the sag on the slack side in the continuous system. In the multiple system the equation for the slack side is true only when the ropes are first spliced on the pulleys, as the stretch in new ropes, when they are put in motion, rapidly increases the sag. Table 3 has been computed from the foregoing equation.

**SHEAVES.**—The larger the sheaves, the less the internal wear of the rope. Sheaves should not be less than 40 times the diameter of the rope for economical wear, and as much larger as it is possible to make them. This rule applies also to idler and tension sheaves.

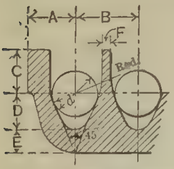

FIG. 4. Driving Sheave Grooves

Fig. 4 and Table 4 show the form and give the dimensions of the grooves in driving and driven sheaves, as recommended by The American Mfg. Co., for the continuous system. The grooves for the multiple rope system are of similar form, but deeper, and the angle of the grooves is 30 deg., instead of 45 deg. Fig. 5 shows the form of grooves recommended for carrier and idler sheaves in the continuous rope system. Grooves should be well polished to avoid wear on the ropes. They also should be free from sand- or blowholes, which tend to cut the rope rapidly.

**COTTON ROPES** are used almost exclusively in Great Britain but only to a limited extent in the U. S., where the preference is for manila rope. The American Mfg. Co. states that cotton ropes are advantageously used as bands or cords on the smaller machine appliances; the fiber, being softer and more flexible than manila hemp, gives good results for small sheaves; but for large drives, where power transmitted is in considerable amounts, cotton rope, as compared with manila, is hardly to be considered, on account of the following disadvantages: It is less durable; it is injuriously affected by the weather, so that for exposed drives, paper-mill work, or use in waterwheel pits, it is unsatisfactory; it is difficult, if not impossible, to splice uniformly; even the best quality cotton rope is much inferior to manila in strength—the breaking strain of the highest grade being but 4000 × diam.$^2$ as against 7000 × diam.$^2$ for manila; while, for the transmission of equal powers, the cost of a cotton rope varies from one-third to one-half more than manila.

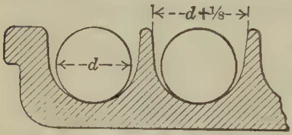

FIG. 5. Idler and Carrier Sheave Grooves

J. Melville Alison (*Jour.* Engg. Inst. of Canada, June, 1920) gives a table for the horsepower transmitted by cotton ropes, from which Table 5 is condensed. He recommends a groove angle in the sheaves of 40 deg.

For many valuable data on rope driving, including arrangement of drives, see Blue Book of Rope Transmission, American Mfg. Co., Brooklyn, N. Y.

**SHEAVE CENTER DISTANCES.**—The distance between the axes of the sheaves of rope drives, where the tight strands are on the bottom, depends on the sheave diameters. The slack strands should clear the tight lower strands by at least 0.1 $L$, where

**Table 4.—Dimensions of Grooves in Rope Sheaves**

$L$ = center to center distance of the sheaves. Where the tight strand is on top, $L$ may be as great as 100 ft., provided that shafts and bearings are sufficiently rugged to withstand the strain of the extra weight of rope. It is not advisable to make the distance between the faces of the sheaves less than 25 ft.

## 2. WIRE ROPE TRANSMISSION

The electrical transmission of energy has largely displaced wire rope as a power transmission medium. For the relatively few installations that require rope, Table 6 will provide the data necessary to calculate the drive. For data on the various types of wire rope available for power transmission, including construction and breaking strength, see pp. 6–34 to 6–43.

**WIRE ROPE SHEAVES.**—Sheaves used with wire rope for the transmission of power are of the form shown in Fig. 6. Dimensions are given in Table 7. The bottom of the sheave is filled with blocks of rubber or leather. The minimum diameter of sheave that should be used with 6 × 7 wire rope is 100 $d$, where $d$ = diameter of rope. With 6 × 19 rope, the minimum sheave diameter should be 66 $d$. Sheaves must be set true on the shafts, and at right angles to the line of transmission to avoid wear on the rope and loss of power. Guide sheaves and supporting sheaves should not be used unless absolutely necessary, for the same reasons. In designing wire rope transmissions to transmit a given horsepower, a choice frequently can be made between small sheaves running at high speed and large sheaves running at a lower speed. Since the wear on the rope always is greater in bending over small sheaves, economy in life of rope will be served by selecting the larger sheaves and lower speeds.

# COUPLINGS AND CLUTCHES

Couplings are of two general classes: 1. Fast or permanent couplings; 2. Releasing couplings, generally known as clutches. Permanent couplings may connect parallel shafts, having a common axis, or otherwise; they may connect shafts having intersecting axes; or they may connect shafts of inaccurate alignment. The positive clutch consists of a part rigidly fastened to the shaft and a second part free to slide along a spline on the shaft. The abutting faces of the coupling engage through interlocking jaws, or drive by friction. For an excellent discussion on couplings and clutches, see Leutwiler's Machine Design. Also see *Trans.* A.S.M.E., xxx, p. 39, 1908.

## 1. COUPLINGS

**BOX COUPLINGS** prevent relative motion of the shafts by means of a key. Unwin gives the proportions shown in Fig. 1.

**A FRICTION COUPLING** that is both simple and effective for small shafts is shown in Fig. 2, which also gives the proportions.

**CLAMP SHAFT COUPLING** (Table 1).—Halsey's Handbook gives the proportions for the clamp shaft coupling shown in Fig. 3. These correspond closely with the proportions of commercial couplings.

**HYDROELECTRIC UNIT COUPLINGS.**—Integrally forged shaft couplings for hydroelectric units have been standardized by the A.S.A. as shown in Fig. 4. Dimensions are given in Table 2.

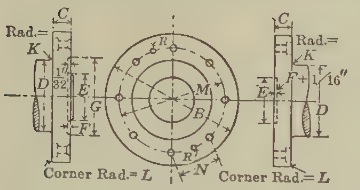

Fig. 4. Integrally-forged Hydroelectric Unit Coupling

**FLANGE COUPLINGS** have not been standardized. The dimensions of stock couplings made by different manufacturers vary considerably. Fig. 5 and Table 3 represent good practice. In these couplings, the center line of the keyway should lie on a diameter through a coupling bolt as shown. Couplings for shafts of 10 in. diameter or over should have two keys 90 deg. apart.

While rules for design are empirical, the resistance of the bolts to the turning movement

Couplings for shaft diameters 7 in. and larger have two jack-bolts *R*. Diameters of bolts are as follows: Shaft diameters, 7 to 12 in., inclusive, 3/4 in.; 13 to 24 in., inclusive, 1 in.; 25 to 38 in., inclusive, 1 1/4 in.; 39 and 40 in., 1 1/2.

of the coupling should exceed the torsional strength of the shaft. The load should be evenly distributed among all the bolts, which will be accomplished by accurately fitting them. Kimball and Barr (Elements of Machine Design) give the following formulas for the diameter and number of bolts:

$$b = 0.5\sqrt{d^3/n}; \quad n = 3 + (d/2)$$

where $b$ = diam. of bolt, in.; $d$ = diam. of shaft, in.; $n$ = number of bolts.

**THE SELLERS COUPLING,** Fig. 6, consists of an outer sleeve bored taper from each end; a split cone bushing fits each end. Through bolts inserted through openings draw the cones toward each other, thus clamping them on the shaft with great force. A key also is provided. If the outer sleeve is made in two parts with an interlocking joint, the coupling is easily adjusted. Table 4 gives proportions.

**FLEXIBLE COUPLINGS** are used to connect shafts that may be subject no more or less misalignment. They are of various forms. Several of the principal types are illustrated below.

**The Flexible Shaft Coupling,** Fig. 7, is suitable for connecting shafts requiring more than ordinary flexibility. The torque, $T$, that can be transmitted is limited by the shearing strength of the flexible steel plate $P$ to resist ring shear at the radius $R$. If $f_s$ = allowable shearing stress of the plate, lb. per sq. in., $T = 2\pi R t f_s$. Usually this value of $T$ will be much less than $^1/_{16}\,\pi d^3 f_s$, the strength of the shaft.

**Leather-link Couplings** are used to connect generators to engines or motors to centrifugal pumps, blowers, etc. They then act as insulators between the connected shafts. Moisture, oil, grit or dust are detrimental to them. The torque of the driving shaft is transmitted to the driven shaft through a combination of flanged cups, links and bolts. Flexibility is obtained by making alternate holes in the flanges large enough to give the bolt sufficient

play to transmit the torque through the leather link. Fig. 8 shows such a coupling made by the Bruce-Macbeth Co., Cleveland. Dimensions and capacities are given in Table 5.

**Leather-laced Couplings** consist of two cast-iron flanges, on each of which is bolted a steel ring with prongs. An endless belt, laced over the prongs, connects the shafts. The machine can be disconnected without unlacing the belt. Fig. 9 shows such a coupling as made by the General Electric Co. Table 6 gives dimensions and capacities.

**The Westinghouse Flexible Coupling** (Fig. 10) consists of two flanged hubs *F*, with rectangular slots cut in the circumference. In each slot is placed a flexible torque-transmitting element comprising a rectangular steel plate *B*, with cushioning material *C* on each side of it. Snap rings prevent radial movement of these elements. Steel cover plates enclose the assembled coupling. Dimensions and capacities are given in Table 7.

**The Meriam Flexible Coupling,** Fig. 11, consists of two hubs connected by hardened steel rollers embedded in a mixture of ground cork, hard grease and graphite. Table 8 gives dimensions and capacities, and Table 9 service factors for different types of applications. These factors are based on electric motor drive and should be increased about 50% for gas or oil engine drive.

**The Oldham Coupling** is used to connect two parallel shafts whose axes are not in the same straight line. The elements of the coupling are shown in Fig. 12. The discs *A* are keyed to the shaft ends, and between them the disc *B* is fitted. Diametral feathers *C* on discs *A* fit in corresponding slots in disc *B*. The feathers on the discs *A* are at right angles to each other. Unwin gives proportions as follows (See Fig. 13), $k = (d + {}^1/_2 \text{ in.})$: $D = 5\,k$; $S = 1.5\,k$; $W = 0.7\,k$; $H = 1.75\,k$; $T = 0.25\,k$; $a = 0.25\,k$; $b = 0.4\,k$. Table 10 gives dimensions and capacities of one commercial type.

**The Morse Flexible Coupling,** Fig. 14, comprises two forged steel hub members mounted on the shafts to be connected, between which is a floating center to which each hub is separately connected through a pair of resilient rubber trunnion blocks 90 deg. apart. The trunnion blocks are set under pressure in a two-piece riveted pressed steel housing, and are permanently fastened to steel bushings. The steel cores in opposite pairs are rigidly bolted to end hub members of the coupling. Flexibility is provided by the resiliency of the rubber cores. Table 11 gives capacities and dimensions.

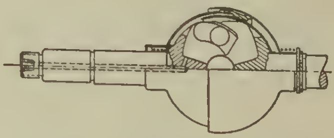

Fig. 17. Weiss Universal Joint

to its rim. Between *A* and *B*, and separated from them by fiber discs, is the flanged hub *C*, keyed to the driven shaft. The bolts connecting the plates *B* with the hub *A* have springs which create a pressure on both faces of the hub *C*. Table 12 (Leutwiler's Machine Design) gives the proportions and other data relative to this type of clutch.

**THE UNIVERSAL JOINT,** also known as a Hooke joint, is used to connect nonparallel shafts which intersect. The joint consists of two U-shaped yokes, fastened to the end of the shafts that are to be connected. A cross-shaped piece, located within these yokes, has four trunnions fitted into bearings on the yokes. Fig. 16 shows the Bocorselski universal joint, as made by the Baush Machine Tool Co., Springfield Mass. Its general dimensions are given in Table 13.

Another form of universal joint, shown in Fig. 17, is the Weiss high-angle joint made by the Weiss Engineering Co., New York. It is designed to maintain a constant velocity, irrespective of the angle of the shafts. In the ordinary universal joint, the angular velocity fluctuates widely as the angle increases. In the Weiss joint, 4 to 8 or more steel balls are placed in intersecting races cut in the joint members. The races guide the balls to precisely half the shaft angle, from zero to its desired maximum, and also compensate for axial movement of the shaft with changes in angle. This joint was primarily developed for automotive use, but has been used in other applications.

## 2. CLUTCHES

Clutches are used to connect shafts to a driving mechanism as a motor, engine or line shaft, and to disconnect them at will. They may be classed as: 1. Jaw clutches, in which jaws of opposed members of the clutch interlock; 2. Friction clutches, in which the driving force is transmitted by the friction of surfaces in contact; 3. Magnetic clutches, in which a magnetizing coil on one member pulls the armature, carrying a friction lining, on the other member into contact with a friction ring on the first member, and thus transmits the torque.

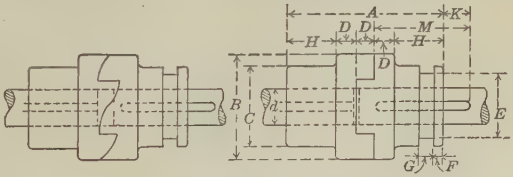

FIG. 18. Jaw Clutches

**JAW CLUTCHES** (Fig. 18) are used for slow-moving shafts, where sudden starting action is not objectionable and when the inertia of the driven parts is relatively small. The various forms of such clutches differ only in the shapes

or angles of the engaging surfaces. One-half of the coupling is fitted with a feather key, permitting it to be engaged with or disengaged from the other half at will.

If $N$ = number of teeth; $R$ = mean radius of clutch tooth; $A$ = area of engaging face of one tooth; $A'$ = area of the tooth subjected to shear; $f_c$ = allowable unit crushing stress of the clutch jaw; $f_s$ = allowable shearing stress of the shaft, then the relation between strength of the shaft and strength of clutch is

$$ {}^1/_{16} f_s \pi d^3 = R N A f_c = R N A' F_s $$

The spiral form, Fig. 18*a*, is more easily put into gear, but the motion of the shaft always must be in the same direction. Low and Bevis give the following proportions (See Fig. 18*b*) for designing cast-iron jaw couplings: $B = 2d + 2$; $C = 1.7d + 1$; $H = 0.5d + 0.5$; $F = 0.3d + 0.3$; $G = 0.4d + 0.4$; clearance between clutch jaws and shaft $= 0.1d + 0.1$. These equations give a heavier clutch than most commercial jaw clutches. Table 14 gives the proportions used by one maker.

**FRICTION CLUTCHES,** which transmit power by the friction of surfaces in contact may be classed: **1.** Disc or plate clutches, either single or multiple; 2. Radial expanding or contracting band or jaw clutches; 3. Conical clutches. The equations used for friction brakes also are applicable to clutches. See p. 15–15.

All types of friction clutches should have torque capacities of double the torque delivered to them in order to start the load from rest without excessive slip. That is, the torque to be transmitted should be multiplied by a static load factor of 2. If the torque delivered to the clutch is irregular, as in certain types of internal combustion engines, the static load factor should be increased from 2 to possibly 3 or 4.

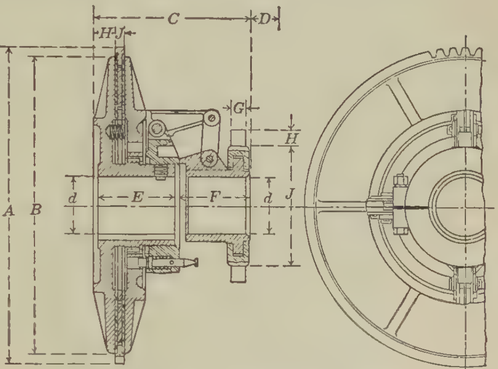

Fig. 19. Single Plate Friction Clutch

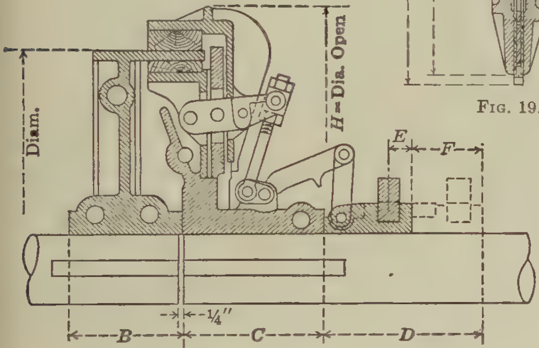

Fig. 20. Radial Jaw Friction Clutch

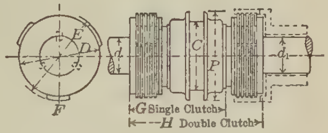

Fig. 21. Multiple-disc Friction Clutch

Additional factors should be applied depending on the character of the load. Table 15 gives factors recommended by the Twin Disc Clutch Co. as a guide in the selection of a clutch based on the characteristics of the driven mechanism.

Example.—Required the torque capacity of a friction clutch to drive woodworking machinery, the prime mover being a 4-cylinder, 40-Hp. Diesel engine running at 1000 r.p.m. *Solution.*—Engine torque $= \{(40 \times 33{,}000)/1000 \times 2\pi)\} \times 12 = 2521$ in.-lb. Diesel engine factor = 3; woodworking machinery factor = 1.75; torque capacity of clutch = 2521 (1.75 + 3.0) = 11,975 in.-lb.

General dimensions and torque capacities of typical heavy-duty single-disc clutches are given in Table 16. Similar information concerning a line of typical multiple-disc clutches is given in Table 17, while Table 18 shows the capacities of one type of radial jaw clutches.

Various materials are used for friction surfaces, but in machine tool applications the tendency is to use hardened steel or phosphor-bronze friction plates. In radial expansion or contraction clutches, the friction surfaces frequently are hard maple and cast iron. Single-plate clutches generally operate without lubricant between friction surfaces (dry type). Multiple-disc clutches are built of the dry type, and also to operate in a bath or spray of oil (wet type).

**Selection of Clutch.**—The type of clutch to be used depends on the service, character of load, space limitations, character of power input, ability to radiate heat and other factors. Single-plate disc clutches generally are used with cranes, gasoline-driven tractors, shovels and similar heavy duty equipment. They also are used in automobiles, for line shaft drives, as are clutches of the radial type, and for various machine applications.

Multiple-disc clutches are used where space is limited, as in machine tool applications, since the same amount of power can be transmitted with two friction discs of a given diameter, as with one disc of twice the diameter. Makers of clutches should be consulted in selecting a clutch for given conditions of service.

**Mounting of Clutches.**—Clutches in industrial work generally are mounted by one of the following methods: 1. The driving plate, to which the friction member is attached, is bolted to the pulley or fly-wheel delivering power to the clutch. The driven element floats on the shaft, either on a splined bushing keyed to the shaft or on splines in the shaft itself. 2. The driving plates and friction discs float on the driving element, which transmits power to it through driving pins, or through an internal toothed ring meshing with gear teeth in the periphery of the driving plate. In some designs a series of projections on the driving plate engage corresponding notches on the driving member. The driven element is rigidly attached to the shaft.

Clutch mountings in automotive work are designed for the special conditions under which they must work.

**The Conical Friction Clutch** consists of the frustum of a cone, so fitted to a shaft by means of a feather key that it can be pushed into an opposite engaging surface rigidly attached to the other shaft. Such clutches require some force to put them into gear. This force, acting parallel to the shaft, produces an undesirable end thrust. Cone clutches may be faced with leather, asbestos fabric, or equipped with cork inserts to increase their driving capacity. The inclination $\alpha$ of the slant side is highly important, in order to avoid "sticking" on the one hand, and too sudden seizure on the other. $\alpha$ usually ranges from 7 1/2 to 13 deg. Proportions may be taken as follows (see Fig. 22*a*): $B = 2\,D + 1$; $C = 1.5\,D$; $F = 1.8\,D$; $H = 0.5\,D$; $E = 0.4\,D + 0.4$; $G = 0.3\,D + 0.3$; $t = 0.2\,D + 0.1$; $L = 2\,D$.

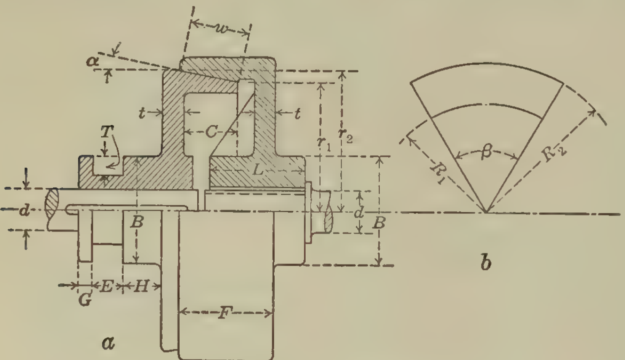

Fig. 22. Conical Friction Clutch

**Formulas for Cone Clutches** (Fig. 22).—Let $M$ = moment clutch is capable of transmitting, in.-lb.; Hp. = horsepower transmitted; $N$ = rev. per min.; $r_1$ = small radius of friction cone, in.; $r_2$ = large radius of friction cone, in.; $r$ = mean radius of friction cone, in.; $V$ = velocity of a point at distance $r$ from center, ft. per min.; $T$ = total tangential force acting at radius $r$, lb.; $P_n$ = total normal pressure between cone surfaces, lb.; $p$ = allowable pressure per sq. in. of contact surface; $P_s$ = total axial or spring pressure, lb.; $\alpha$ = angle of clutch surface with axis of shaft; $\mu$ = coefficient of friction; then

$$r = {}^1\!/_2\,(r_1 + r_2);\ M = T\,r;\ T = \mu P_n;\ V = {}^1\!/_{12}\,(2\,\pi\,r\,N);\ W = P_n/(2\,\pi\,r\,p).$$

For engagement without slip,

$$\text{Hp.} = P_n \mu\, r\, N/63{,}030;\ P_s = (T/\mu)(\sin\alpha + \mu\cos\alpha) = \text{Hp.} \times 63{,}030\{(\sin\alpha + \mu\cos\alpha)/\mu\, r\, N\}$$

and $$P_n = P_s/\sin\alpha, \quad \text{and} \quad P_s = (\text{Hp.} \times 63{,}030\,\sin\alpha)/\mu\, r\, N.$$

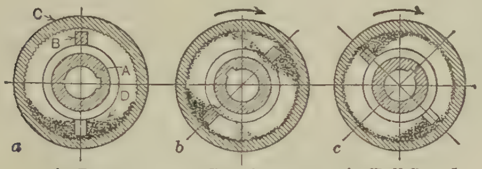
If the cone is to be leather covered (see Fig. 22*b*), then

$$R_1 = r_1/\sin\alpha;\ R_2 = r_2/\sin\alpha;\ R_2 - R_1 = w;\ \beta = \sin\alpha \times 360.$$

The allowable normal pressure $p$, lb. per sq. in., may be taken as 7 or 8 lb. for leather bands, according to *Machinery's Handbook;* Smith and Marx give values of 30 to 40 lb. for leather or cork, and 35 to 45 lb. for maple wood. For values of $\mu$, see Table 1, p. 8–24.

**THE RAMSEY-PULVIS CLUTCH** is a unique form of clutch designed to start a load without shock. The principle is shown in Fig. 23. The rotor $A$, keyed to the driving shaft, has two diametrically opposite blades or paddles $B$ that extend almost to the serrated inner circumference of shell $C$ which is attached to the driven shaft. Hardened steel shot is introduced into the annular space between the rotor and shell. When rotor $A$ is started, the paddles *B* lift the shot as shown in Fig. 23 *b*. As the rotor increases in speed, centrifugal force throws a portion of the shot outward where it is trapped between the serrations in the shell and the ends of the blade causing the shell to start turning. Still further increase in speed causes additional shot to be thrown outward, the several layers interlocking with each other and with the serrations in the shell until they form practically two solid masses as shown in Fig. 23 *c*. The shell and rotor then are in synchronism. The action of the shot as the shell comes up to speed is virtually that of conversion from a fluid to a solid condition.

This clutch is made in several forms for attachment to different types of mechanism. It may be used as a pulley mounted directly on a motor shaft, the shell forming the pulley face. It also may be used as a coupling between two shafts in the same straight line, the shell driving through friction members or studs. Dimensions of the pulley type are given in Table 19 and horsepower ratings in Table 20. This clutch is made by the Ramsey Chain Co., Albany, N. Y.



At Rest Starting At Full Speed

**MAGNETIC CLUTCHES** are a form of friction clutch in which the friction surfaces are brought into contact by an electromagnet instead of by mechanical means. They may be operated at higher rotative speeds than mechanical clutches, and are recommended for heavy duty where the latter are impractical, for high-speed drives, and where the motor cannot start a heavy load. The principle of the clutch is shown in Fig. 25. A magnet coil *A*, carried by one member of the clutch, attracts to itself the armature *B* carried by a spring plate *C*, which flexes when the magnet is energized. A friction ring *D* carried by the armature is faced with friction lining *F*. When the coil *A* is energized the friction lining is drawn into contact with field friction ring *E*. The friction between *E* and *F* transmits the torque from one clutch member to the other. For heavy duty, two friction linings often are used. See Figs. 27 and 28.

The clutch is engaged by energizing the magnet coil, and disengaged by de-energizing it. The spring plate then pulls the friction lining away from the friction ring until there is an idling clearance of about $^1/_{16}$ in. between them. The current in the magnet coil is varied by a manually-operated controller, which permits the torque to be built up gradually. Heavy loads thus can be started without shock.

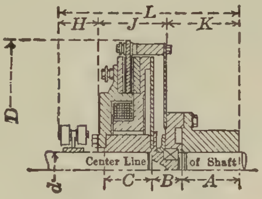

FIG. 27

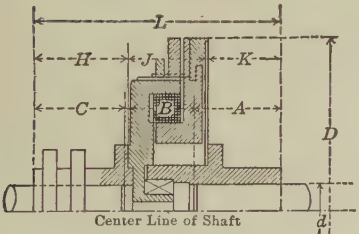

FIG. 26.

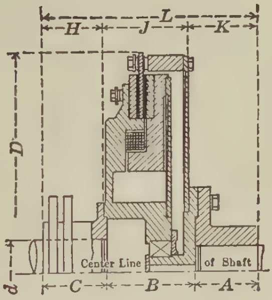

FIG. 28

Dimensions and capacities of magnetic clutches are given in Table 21.

**SLIP RING STARTER.**—A device known as a slip ring starter, developed by the Bethlehem Steel Co., Bethlehem, Pa., may be used to start slowly machinery with heavy inertia load, driven by constant-speed motors. It also may be used as a flexible coupling. The starter depends on the action of centrifugal force to produce pressure between the friction surfaces of the driving and driven members. The construction is shown in Fig. 29. The driving member *A* is keyed to the motor shaft. The driven member *B* is keyed to the machine shaft. Pins *C* project from the driving member *A*, and transmit motion to the interrupted friction rings *F* through the balls *D*. Attached to the friction rings *F* at regular intervals are the weights *E*. Two rings are used in order to balance the drive, and the pins *C* are at opposite edges of a diametral plane. The construction shown in Fig. 29 provides for rotation in one direction only. For rotation in both directions, another set of pins *C* would be provided, which would engage the other ends of the friction rings *F*. A cover *G*, held in place by a spring wire retaining ring *H*, encloses the mechanism.

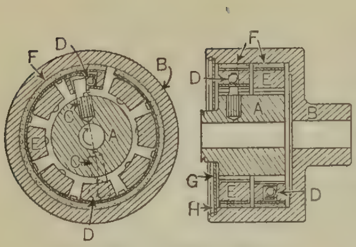

FIG. 29. Slip Ring Starter

In operation, the starting of the motor causes the friction rings to be rotated by the pins *C*. As the speed increases, centrifugal force expands the friction rings until they are in contact with the sleeve *B*. They slip on the sleeve until the pressure due to centrifugal force is sufficient to develop the maximum torque of the friction material, after which the drive operates without slip. The drive normally is designed to transmit 125% of the rated horsepower of the motor, but can be built to transmit any required torque at a specified speed by variation in the weights *E*. The drive will slip under an overload greater than that for which it is designed, but operates as a positive drive as soon as normal conditions are resumed. The torque transmitted at a given speed is not affected to any material extent by variation in the coefficient of friction.

**SHIFTING GEAR FOR CLUTCH COUPLINGS.**—The usual means of engaging or disengaging clutch couplings is a forked lever, whose prongs fit the grooves in the sliding part of the coupling. (See Fig. 30.) Table 22, condensed from *Machinery's Handbook* gives standard dimensions.

# SPEED CHANGING MECHANISMS

Speed changing mechanisms are of two general classes: 1. Those in which the ratio of speeds of driving and driven members is fixed, generally known as *speed reducers;* 2. Those in which the ratio of speeds of driving and driven members can be varied at will, generally known as *variable speed drives.* The belt and cone pulley also is, strictly speaking, a speed changing device. See p. 24–12.

## 1. SPEED REDUCERS

**SPEED REDUCERS** comprise, generally, either one or more pairs of spur or herringbone gears, enclosed in a suitable case, or a worm and worm wheel. Another type of speed reducer consists of two sprockets connected by either roller or silent chain.

**Geared Speed Reducers** usually are made with herringbone gears to eliminate all end thrust. The single reducers employ one pair of gears, the pinion being on the input or driving shaft. The *double reduction unit* employs two pairs of gears, the pinion on the input shaft meshing with a gear on an intermediate shaft. The other end of this shaft

23 to 30 deg. Splash lubrication generally is used for gears and bearings. Table 1 and Figs. 1 and 2 give dimensions of a typical line of herringbone gear reducers. Tables 2 and 3 give capacities.

### Table 3.—Horsepower Transmitted by Double Gear Speed Reducers

(Link-Belt Co., Chicago)

**Table 5.—Service Factors for Worm Gear Reducers***

| Class of Service | Drive | | |
|---|---|---|---|
| | Motor; Turbine | Steam Engine; 4-cyl. Gas or Oil Engine | 1- or 2-cyl. Gas or Oil Engine |
| Steady load, as centrifugal blowers, centrifugal pumps, forced draft fans | 1 | 1.5 | 2 |
| Slightly fluctuating load, as liquid agitators, induced draft fans, rotary pumps and blowers, line-shaft drives, freely starting conveyors | 1.25 | 1.75 | 2.25 |
| Widely fluctuating load, as plastic agitators, paper mill beaters, bucket elevators, machine tool drives, rubber calenders, conveyors starting under load, stokers | 1.5 | 2. | 2.5 |
| Vibrating load, as rotary kilns, rotary dryers, skip hoists, cranes, punch presses | 1.75 | 2.25 | 2.75 |
| Shock loads, as rolling mills, ball and bar mills, crushers, single cylinder pumps, air compressors, screw presses | 2 | 2.25 | 3 |

* Occasional overloads up to 40 and 80% should take service factors one and two classes larger than that used for the same service without overloads. For high-starting torque loads, the drives should have a capacity of not less than 50% of the starting peak load.

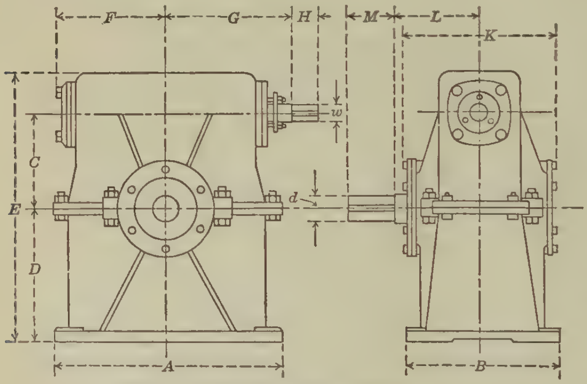

FIG. 3. Worm Gear Speed Reducer

**Worm Gear Reducers** are made in various forms. In general, they comprise an alloy steel worm mating with a phosphor-bronze worm wheel, which may be integral, or in larger sizes may be mounted on an iron or steel center. Splash lubrication generally is employed. As a rule, the reducer is connected to the motor and driven mechanism by means of flexible couplings. Table 4 and Fig. 3 give dimensions of a typical worm gear reducer. Table 6 gives capacities. Where the load is other than a steady one, the service factors in Table 5 should be applied.

## 2. VARIABLE SPEED DRIVES

The earliest type of variable speed drive consisted of a pair of similar cones, set with their axes parallel, the large diameter of one cone being alongside the small diameter of the other. A friction ring of flexible material encircled one cone and engaged the surface of the other. One cone being the driver, the speed of the other cone could be varied by moving the friction ring axially. This principle of driving contact with different diameters on two conical surfaces forms the basis of the more modern variable speed drives, some of which are described below.

**THE P. I. V. GEAR** uses a positive chain drive to transmit power. The gear is shown diagrammatically in Fig. 5. It consists of the two pairs of conical discs *A* with radial teeth cut on the conical face, mounted on the splined shafts *B* on which they are free to slide axially. The bearings *C* are carried on levers *D*, which are pivoted at *E* midway

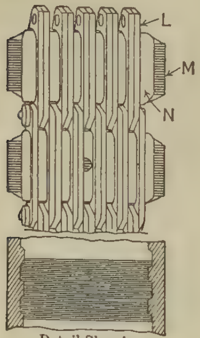
between the bearings of the two conical wheels. A right- and left-hand screw *F* connects the two levers *D*. Rotation of this screw causes the discs *A* on one shaft to approach each other while those on the other shaft recede by a corresponding amount. The two wheels are connected by means of the drive chain *G*, details of which are shown in Fig. 4. The chain is made up of a series of overlapping steel links *L* with hardened steel pin joints. Attached to the wheel side of the links are containers *N*, which hold packs of hardened steel laminations *M* at right angles to the link, projecting about $^1/_8$ in. from either side of the chain. These laminations are free to slide from side to side individually, and adjust themselves to engagement with the radial teeth on the discs *A* over the full range of diameter, as shown in detail in Fig. 5. The teeth are staggered on the opposing faces of each pair of discs.



Detail Showing Action of Links

Fig. 4. P.I.V. Gear Drive Chain

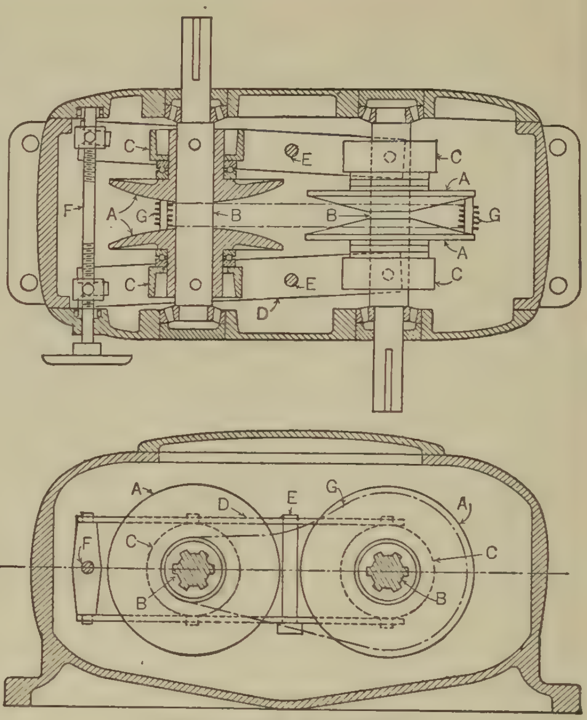


Fig. 5. P.I.V. Gear Principle

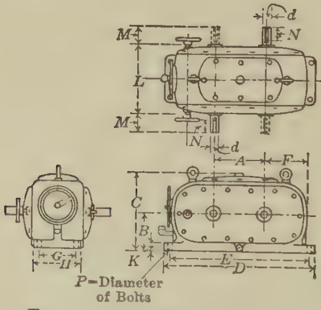

Fig. 6. P.I.V. Horizontal Gear

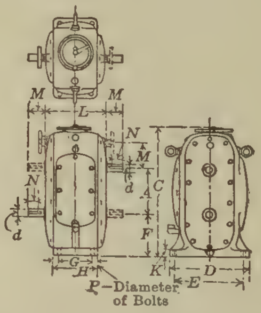

Fig. 7. P.I.V. Vertical Gear

As the distance between the faces of a wheel is increased the links engage with them on a smaller working diameter. The working diameter of the mating wheel is correspondingly increased, thus providing speed variations between the two shafts in any ratio desired up to the limiting ratio of the particular drive in use.

These drives are built both in horizontal and vertical types, for driving by roller or silent chain on the constant-speed shaft. They also are built with a motor integral with the drive and geared to the constant-speed shaft. Another form that is regularly built is provided with gear reducers on either the constant or variable speed shafts, or on both. This gear is built by the Link-Belt Co., Chicago. Dimensions and horsepower capacities are shown in Tables 7 and 8 and Figs. 6 and 7.

**THE REEVES VARIABLE-SPEED TRANSMISSION** (Figs. 8 and 10) consists of two pairs of cone-shaped discs mounted on spline shafts. The discs are carried in bearings on the levers *V*, pivoted at *P*. The hand wheel *W* actuates the right- and left-hand screw *S* causing the levers to rotate about *P*, and thus causing the discs of one pair to approach and of the other pair to recede from each other as desired. One shaft is connected to the driving motor, or other prime mover. The other is connected to the driven mechanism. A rubber belt, with blocks of hard wood bolted to each face, connects the two pairs of discs. See Fig. 9. The ends of the blocks are finished at the same angle as that of the discs. The driving force is the friction between the blocks and the disc

faces. When the discs of one pair are widely separated, the diameter of the circle of contact with the blocks is small, while it is correspondingly large on the other pair. By varying the distance between the discs any desired speed ratio between the driving and driven shafts can be obtained, within the range of the transmission.

These transmissions are built by the Reeves Pulley Co., Columbus, Ind., in both horizontal and vertical types, and both open and enclosed. Capacities range up to 100 Hp. It should be remembered that the horsepower transmitted varies with the speed of the driven shaft. A transmission that will deliver the requisite horsepower at the maximum speed, may be unable to deliver it at the lowest speed, and a larger drive is indicated. Table 9 gives data for the selection of the proper size of transmission for a

given set of conditions. The table is entered opposite the horsepower that is to be transmitted. In the column under the desired speed ratio is the size of the drive recommended, and also the speed of the constant-speed shaft, and the maximum and minimum speeds of the variable speed shaft. The factor $M$ is used to determine the maximum and minimum speeds of the variable speed shaft, when the constant-speed shaft runs at other than the recommended speed. If $N$ = r.p.m. of constant-speed shaft, and $n_h$, $n_l$ = respectively the maximum and minimum speeds of the variable speed shaft, $n_h = N \times M$; $n_l = N/M$.

Table 10 gives dimensions of open-type transmissions.

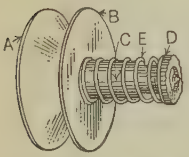

Fig. 11. Reeves Vari-speed Pulley

**The Reeves Vari-speed Pulley** is designed to replace the ordinary flat pulley on motors up to 7 1/2 Hp., to vary the speed of the driven mechanism. It operates on the same principle as the Reeves variable speed drive (see p. 24–75). The pulley (Fig. 11) consists of two discs $A$ and $B$ mounted on a shaft $C$, disc $B$ being free to move axially on the shaft. Its distance from disc $A$ can be regulated by the hand nut $D$. The spring $E$ holds it against the belt with a constant tension. The edges of the belt, which are beveled to the same angle as the discs, bear against the discs. The flat side of the belt bears on face of the driven pulley. As the distance between the discs is increased the working diameter of the belt on the discs is decreased, thus altering the speed ratio. Table 11 gives dimensions and capacities.

**THE GRAHAM VARIABLE SPEED TRANSMISSION** is based on the principle of a ring of fixed diameter in contact with conical rollers, the speed ratio depending on the ratio of the diameter of the ring to the diameter of the rollers at the point of contact. Fig.12 is a diagrammatic arrangement of the drive. Three conical rollers $A$

‡ In reverse.

are carried in the carrier $B$, spaced 120 deg. apart. The rollers $A$ bear with fixed pressure against the contact ring $C$ which surrounds the carrier. The position of $C$ can be varied axially by means of the rack $D$ and the pinion $E$. The carrier $B$ is attached to the drive or input shaft. The rollers $A$ carry, at their small ends, pinions $F$ which mesh with an internal gear $G$, attached to the driven or output shaft. In operation, as the carrier $B$ is rotated, it causes the rollers $A$ to revolve around the center-line of the carrier. The friction between the rollers and the contact ring $C$ causes the rollers to rotate about their own axes, and in turn to drive the output shaft through the pinions and gear $F$ and $G$. The rate of rotation of the rollers, and consequently the speed of the output shaft, depends on the position of the contact ring $C$. The speed of the driven shaft is lowest when the ring is in contact with the smallest diameter of the rollers, and highest when it is in contact with the largest diameter. An indicator on the front of the case shows the position of the contact ring, and the speed ratio at which the drive is operating.

Table 12 gives the capacity of drives up to 7 1/2 Hp. and the maximum and minimum speeds. In the Type $E$ drive, the speed variation is from maximum through zero and into reverse. In the type $N$ drive, the speed variation range is about 4 : 1. The drive may be operated by a built-in motor, or motor coupled to the input shaft. It also is made with a built-in geared head on the output end which reduces the speed of the output shaft to 1/7 of the values given in Table 12, and increases the torque 7 times. This drive is made by Graham Transmissions, Springfield, Vt. Table 13 and Fig. 13 give dimensions.

## 3. HYDRAULIC DRIVES

**THE HYDRAULIC COUPLING**, built by the Hydraulic Coupling Corporation, Detroit, is a development of the Vulcan Sinclair fluid transmission. It is used as a variable speed transmission between centrifugal fans and the driving motor. The principle of operation is shown in Fig. 14. The vaned impeller $A$ is attached to the driving shaft of the motor. The runner $B$, similarly vaned, surrounded by an inner casing $C$, is attached to the driven shaft, which may be the fan shaft or the shaft of any other mechanism. The passages $D$ in runner and impeller correspond, and form a continuous circuit or vortex ring between the two elements. The system is filled with oil, which, under the influence of centrifugal force, is discharged from the impeller against the runner, which causes the runner to rotate. The speed of the runner, when the system is filled with oil, is from 1% to 3% less than that of the impeller. This slip sets up a vortex in the vortex ring, pumping the oil around as shown by the arrows, and thus maintains the torque.

Oil leaking from between the runner and impeller flows into the passage between the runner and the inner casing, and is discharged through calibrated ports $E$ into the space between the inner casing and the outer casing $K$. This oil is picked up by the scoop tube $G$ and returned through ports into the vortex ring as shown by the arrows. Speed variation is effected by varying the amount of oil in the system. This is accomplished by the pump $H$, which removes a portion of the oil as it passes the pump connection, and stores it in tank $K$. Maximum speed

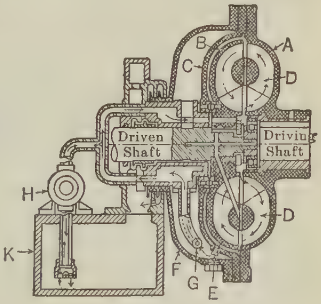

Fig. 14. Principle of Hydraulic Coupling

is obtained with the system full of oil. With all oil removed from the system and stored in the tank a minimum of power is transmitted, the active fluid then being air contained in the vortex ring. To increase the speed of the driven shaft, the pump *H* is reversed and oil is restored to the system. Speed may be infinitely varied from maximum to minimum by varying the amount of oil in the vortex. Instead of the storage tank *K*, in which the supply and removal of oil is effected by a pump, an elevated tank is used for certain types of service. Oil picked up by the scoop tube is led to the elevated tank. It is returned to the coupling by gravity through a calibrated weir, which can be raised or lowered manually or automatically in accordance with the speed control desired.

The heat generated inside the coupling under moderate speed, and load conditions usually is dissipated by radiation from the surface of the coupling. Under heavy loads at high speeds, or when $S\,(V/1000)^3 > 600$, an oil cooler is necessary. $S$ = slip, and $V$ = peripheral velocity.

The efficiency with 3% slip is about 96.5%, which includes windage and heat loss. For average conditions of operation, a slip of about 2% usually is most satisfactory. Fig. 15 shows the brake horsepower output of various sizes of couplings at various motor speeds, and also at various tip speeds based on inside of diameter of coupling. This chart is based on a coupling filled with oil.

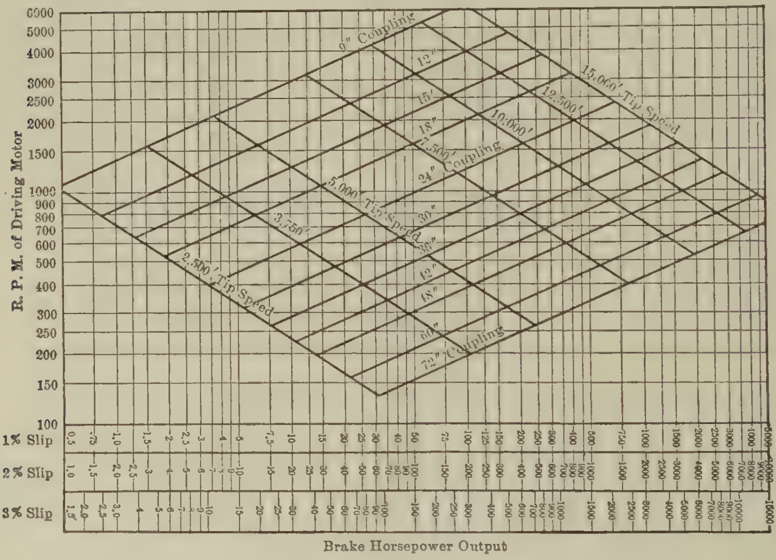

FIG. 15. Brake Horsepower Output of Hydraulic Couplings

To select a coupling, enter Fig. 15 with the required horsepower at the assumed slip. At the intersection of this ordinate with the abscissa representing motor speed, find the size coupling required. The coupling is selected for the maximum rating of the fan. For other ratings, the procedure is as follows: Calculate the constants $K_c$, $K_r$ and $K_p$ representing, respectively, cu. ft. per min. delivered by the fan, rev. per min. of the fan, and resistance pressure at full motor speed.

$K_c = Q/(100-S)$; $K_r = N/(100-S)$; $K_p = P/(100-S)^2$, where $Q$ = cu. ft. per min. at full motor speed; $S$ = slip; $N$ = r.p.m. of fan; $P$ = resistance pressure, in. of water. Then if $Q_1$, $N_1$ and $P_1$ = respectively, the cu. ft. per min. rev. per min., and resistance pressure at any speed other than full speed, and $n$ = fan speed, expressed as a percentage of full speed.

$$Q_1 = K_c \times n;\ \ N_1 = K_r \times n;\ \ P_1 = K_p \times n^2.$$

Motor Hp. = Fan B.Hp. × *f*, in which *f* is a factor whose value is as follows:

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| Fan speed, % of constant motor speed = | 100–S | 90 | 80 | 70 | 60 | 50 | 40 | 30 | 20 |
| *f* = | 1.04 | .885 | .70 | .545 | .405 | .282 | .182 | .105 | .052 |

**Example.**—Select a coupling for a fan delivering 140,000 cu. ft. per min. at 14 in. resistance pressure; fan speed 859 r.p.m.; brake horsepower required 478. Determine the fan r.p.m., resistance pressure, and B.Hp. at 90%, 70%, 50% and 30% of maximum fan speed.

*Solution.*—From Fig. 15, a No. 36 coupling will be satisfactory with a slip of 1.2%. Then

$$K_c = 140{,}000/(100 - 1.2) = 142{,}500$$
$$K_r = 859/(100 - 1.2) = 875 = \text{motor speed}$$
$$K_p = 14/(100 - 1.2)^2 = 14.5$$

| | | | | |
|---|---|---|---|---|
| $n =$ | 0.90 | 0.70 | 0.50 | 0.30 |
| $f =$ | .885 | .545 | .282 | .105 |
| $Q_1 = K_c \times n =$ | 128,000 | 100,000 | 71,400 | 42,800 |
| $N_1 = K_r \times n =$ | 787 | 612 | 437 | 262 |
| $P_1 = K_p \times n^2 =$ | 11.8 | 7.1 | 3.6 | 1.3 |
| $\text{B.Hp.}_1 = \text{B.Hp.}_{\text{max.}} \times f =$ | 423 | 261 | 135 | 50 |

Dimensions of standard hydraulic couplings are given in Table 14 and Fig. 16.

**THE THRUSTOR,** while not a speed changing device, is a hydraulic mechanism to produce thrust in a straight-line direction. The principle of the thrustor is shown in Fig. 17. A piston *P* contained in a cylinder *C* filled with oil, is connected by two piston rods to the yoke *Y*. A motor *M* drives the centrifugal pump *U* at the bottom of the cylinder, setting up a pressure on the under side of the piston and causing it to rise. Oil is drawn by the pump from the upper part of the cylinder through the tube *C*. When the motor is stopped, the weight of the piston causes it to descend, the oil flowing back through the pump to the upper part of the cylinder.

The thrustor is made by the General Electric Co. It is used to control brakes and clutches on punch and drawing presses, to operate arbor presses, to apply pressure to the work in spot welders, to operate brakes on various types of equipment, to operate valves, to open and close doors on furnaces, elevators, etc. It is used wherever straight line motion is required, or pressure is to be applied. In connection with a pawl and ratchet it can be used to bar engines or to give practically continuous rotary motion. By means of appropriate linkwork, the direction of motion of the thrustor can be changed, transformed or multiplied as desired.

Capacities of thrustors range from 50 lb. thrust with a 2-in. stroke to 3200 lb. thrust with a 16-in. stroke. The pressure varies as the square of the speed of the motor. The speed of movement depends on the load.

# DYNAMOMETERS

Dynamometers are instruments used for measuring power. They are of several classes, as: 1. Traction dynamometers, used for determining the power required to pull a car or other vehicle, or a plow or harrow. 2. Brake or absorption dynamometers, in which the power of a rotating shaft or wheel is absorbed or converted into heat by the friction of a brake or into electrical energy, and 3. Transmission dynamometers, in which the power in a rotating shaft is measured during its transmission through a belt or other connection to another shaft, without being absorbed.

**TRACTION DYNAMOMETERS** generally contain two principal parts: 1. A spring or series of springs, through which the pull is exerted, the extension of the spring measuring the pulling force; 2. A paper-covered drum, rotated either at a uniform speed by clockwork, or at a speed proportional to the speed of the traction, through gearing, on which the extension of the spring is registered by a pencil. The average height of the diagram above the zero-line gives the average pulling force in pounds. This multiplied by the distance traversed, in feet, gives the work done, in foot-pounds. The product divided by the time in minutes and by 33,000 gives the horsepower.

**THE PRONY BRAKE** is the typical form of absorption dynamometer. Primarily this consists of a lever so connected to a revolving shaft or pulley that the friction induced between the surfaces in contact will tend to rotate the arm in the direction in which the shaft revolves. This rotation is counterbalanced by a weight-measuring apparatus, as a platform scale, one or more spring balances, or simply by weights hung in a pan at the end of the lever arm attached to the friction surfaces. See Fig. 1. The friction blocks *B* are of wood, and are confined by the strap which can be tightened on them, to increase the friction on the wheel, by means of the bolt *C*. The lever *D* is bolted to the band *A* and bears on the scale as shown. The heat generated by the friction is carried off by water introduced inside the rim, and removed by the outlet pipe which is so shaped as to scoop the water from the rotating wheel. The downward pressure of the lever arm is balanced by the weights *W* on the platform scale.

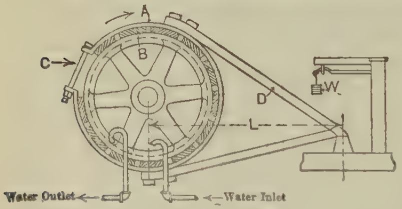

Fig. 1. Prony Brake

If $L$ = horizontal length of lever arm, ft., $N$ = rev. per min. of wheel, $W$ = weight required to balance the downward pressure of the lever arm, lb., $w$ = tare of brake, lb. = weight on scales with apparatus at rest, and Hp. = the horsepower of the shaft or mechanism to which the brake is attached, then

$$\text{Hp.} = 2\pi LN(W - w)/33{,}000 = (W - w)\,N/K, \quad . \quad . \quad . \quad . \quad [1]$$

where $K = 33{,}000/2\pi L$. If $L = 33/2\pi = 5\ {}^1/_4$ ft. (approx.), then Hp. = $1000WN$.

If the rubbing-surface be too small, the resulting friction will show great irregularity, probably because of insufficient lubrication, the blocks will seize the pulley and thus produce shocks and sudden vibrations of the lever-arm.

Soft woods, as bass, plane-tree, beech, poplar, or maple, are all to be preferred to the harder woods for brake-blocks. The blocks should be spaced at least $^1/_4$ in. apart. The rubbing surface should be well lubricated with a heavy grease.

Another form of Prony brake is a pair of blocks or jaws, gripping the shaft. The blocks should extend around the greater part of the circumference. A pair of bolts through the blocks on either side of the shaft serves to tighten the blocks on the shaft. A lever-arm of any desired length is attached to the upper block and bears on a platform scale or is supported by a spring balance. The horsepower is computed by formula [1].

**Rope Brake.**—For small amounts of power, the Prony brake may consist simply of a rope or strap wrapped around the brake wheel, one end being fastened to the floor or some other immovable part of the structure, through a spring balance and the other end attached to a second spring balance or weighted. See Fig. 2. If $W$ and $w$ are, respectively the net applied weight and the net spring balance reading, and $R$ is the radius of the brake wheel in feet, then

$$\text{Hp.} = 2\pi R N(w-W)/33{,}000 \quad . \quad . \quad . \quad . \quad [2]$$

Prony brakes are suitable only for the measurement of relatively small powers, say up to about 100 Hp. and for speeds of not over 1000 r.p.m. For greater horsepower and higher speeds a water brake or electric dynamometer should be used.

**CAPACITY OF FRICTION-BRAKES.**—W. W. Beaumont (*Proc. Inst. C. E.*, 1889) has deduced a formula by means of which the relative capacity of brakes can be compared, based on the amount of horsepower ascertained by their use.

Let $W$ = width of rubbing-surface on brake-wheel, in.; $V$ = velocity of point on circumference of wheel, ft. per min.; $K$ = coefficient; then

$$K = WV \div \text{Hp.} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad [3]$$

Prof. Flather obtained the values of $K$ given in Table 1. Calculations for eleven brakes gave values of $K$ varying from 84.7 to 1385 for actual horsepowers determined, the average being $K$ = 655. Instead of assuming an average coefficient, Prof. Flather recommends the following:

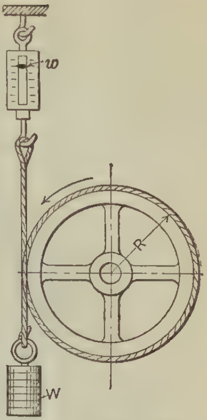

FIG. 2. Rope Brake

Water-cooled brake, non-compensating, $K$ = 400; $W$ = 400 Hp. ÷ $V$.
Water-cooled brake, compensating, $K$ = 750; $W$ = 750 Hp. ÷ $V$.
Non-cooling brake, with or without compensating device, $K$ = 900; $W$ = 900 Hp. ÷ $V$.

F. A. Halsey (*Am. Mach.*, April 4, 1912), advises a minimum brake-drum surface for water-cooled Prony brakes of 0.09 sq. ft. per brake Hp. to avoid the danger of the blocks taking fire.

A brake described in *Am. Mach.*, July 27, 1905, had an iron water-cooled drum, 30 in. diam., 20 in. face, with brake blocks of maple attached to an iron strap nearly surrounding the drum. At 250 r.p.m., or a circumferential speed of 1963 ft. per min., the limit of its capacity was about 140 Hp.; above that power the blocks took fire. At 140 Hp. the total surface passing under the brake blocks per minute was 3272 sq. ft., or 23.37 per Hp. This corresponds to a value of $K$ = 285.

**ABSORPTION DYNAMOMETERS.**—The two types of absorption dynamometers in general use are the water brake, exemplified by the Alden and Froude dynamometers, and the electric dynamometer.

**The Alden Absorption-Dynamometer** (G. I. Alden, *Trans.* A.S.M.E., xi, p. 958; also xii, p. 700 and xiii, p. 429.) is a friction-brake, capable in moderate sizes of absorbing large powers with unusual steadiness and complete regulation. A smooth cast-iron disc is keyed on the rotating shaft. This is enclosed in a cast-iron shell, formed of two discs and a ring at their circumference, which is free to revolve on the shaft. To the interior of each of the sides of the shell is fitted a copper plate, enclosing between itself and the side a water-tight space. Water under pressure is admitted into each of these spaces, forcing the copper plates against the central disc. The chamber enclosing the disc is filled with oil. To the outer shell is fixed a weighted arm, which resists the tendency of the shell to rotate with the shaft, caused by the friction of the plates against the central disc. See *Trans.* A.S.M.E., xi, p. 958; xii, p. 700; xiii, p. 429.

**Table 1.—Values of $K$ for Various Types of Friction Brakes.**

| Horse-power | R.p.m. Brake Pulley | Brake Pulley | | Length of Arm, in. | Design of Brake | Value of $K$ |
|---|---|---|---|---|---|---|
| | | Face, in. | Diam., ft. | | | |
| 21 | 150 | 7 | 5 | 33 | Royal Ag. Soc., compensating | 785 |
| 19 | 148.5 | 7 | 5 | 33.38 | McLaren, compensating | 858 |
| 20 | 146 | 7 | 5 | 32.19 | McLaren, water-cooled and compensating | 802 |
| 40 | 180 | 10.5 | 5 | 32 | Garrett, water-cooled and compensating | 741 |
| 33 | 150 | 10.5 | 5 | 32 | Garrett, water-cooled and compensating | 749 |
| 150 | 150 | 10 | 9 | ........ | Schoenheyder, water-cooled | 282 |
| 24 | 142 | 12 | 6 | 38.31 | Balk | 385 |
| 180 | 100 | 24 | 5 | 126.1 | Gately & Kletsch, water-cooled | 209 |
| 475 | 76.2 | 24 | 7 | 191 | Webber, water-cooled | 847 |
| 125<br>250 | 290<br>250 | 24 | 4 | 63 | Westinghouse, water-cooled | 465 |
| 40<br>125 | 322<br>290 | 13 | 4 | 27 3/4 | Westinghouse, water-cooled | 847 |

Four brakes of this type, 56 in. diam., were used in testing the experimental locomotive at Purdue University. Each was designed for a maximum moment of 10,500 ft.-lb. with a water-pressure of 40 lb. per sq. in. The area in effective contact with the copper plates on either side is represented by an annular surface with an outer radius of 28 in. and an inner radius equal to 10 in. The apparent coefficient of friction between the plates and the disc was 3 $^1/_2$%.

**The Froude Dynamometer,** made by C. H. Wheeler Mfg. Co., Philadelphia, is a water brake, consisting of a rotor keyed to the shaft and rotating in a casing. Both rotor and casing have pockets in their faces, separated by vanes. The friction of the water tends to cause the casing to rotate simultaneously with the impeller, which tendency is resisted by a lever arm fixed to the casing and bearing on a weight-measuring apparatus. The horsepower is calculated by formula [1]. These dynamometers are regularly built to measure up to 5000 Hp. at 250 r.p.m., and 300 Hp. at 4000 r.p.m.

In these dynamometers, the water should be supplied under a constant pressure of from 10 to 30 lb. per sq in., gage, preferably from an overhead tank in which a float valve maintains a constant water level. The quantity of water required depends on the temperature of the water. With water at 70° F. a minimum supply of about 3 gal. per brake Hp.-hour should be maintained, and about 4 gal. per brake Hp.-hour with water at 100° F. These figures are based on the water leaving the dynamometer at 180° F.

**The Electric Dynamometer** made by the Sprague Works of the General Electric Co. is a device for measuring dynamic torque, which may be used either as an absorption element or as a prime mover. In both cases the power shaft of the apparatus under test is coupled to the shaft of the internally revolving rotor of the dynamometer which transmits the full torque exerted by or on that shaft to the external floating frame by electro-magnetic interaction. The floating field is balanced in anti-friction bearings and is restrained from revolving by scales on which the torque is measured directly. The full torque developed by the dynamometer (as a motor) or delivered to it by a prime mover (as a brake) is recorded on the scales. These dynamometers are made in capacities of from 4 to 1000 Hp., with maximum speeds up to 5000 r.p.m.

The horsepower formula is, as before, Hp. = $2\pi NWL/33{,}000 = WN/K$. For a 15 $^3/_4$ in. arm $K = 4000$; for a 21 in. arm $K = 3000$. The adjustment of the torque or speed is accomplished by a dual control of current strength in the rotor and stator windings. This dual control permits the speed to be adjusted through successive increments of the closest reading speed indicator from zero to maximum speed and the torque to any intermediate value between maximum and a minimum of nearly zero.

**TRANSMISSION DYNAMOMETERS** are of various forms, as the Batchelder dynamometer, in which the power is transmitted through a "trained-arm" of bevel gearing, with its modifications, as the one described by William Kent in *Trans.* A.I.M.E., viii, p. 177, and the one described by Samuel Webber in *Trans.* A.S.M.E., x, p. 514; belt dynamometers, as the Tatham; the Van Winkle dynamometer, in which the power is transmitted from a revolving shaft to another in line with it, the two almost touching, through the medium of coiled springs fastened to arms or discs keyed to the shafts; the Brackett and the Webb cradle dynamometers, used for measuring the power required to run dynamo-electric machines. Descriptions of the four last named are given in Flather on Dynamometers.

The Kenerson transmission dynamometer is described in *Trans.* A.S.M.E. 1909. It has the form of a shaft coupling, one part of which contains a cavity filled with oil and covered by a flexible copper diaphragm. The other part, by means of bent levers and a thrust ball-bearing brings an axial pressure on the diaphragm and on the oil, and the pressure of the oil is measured by a gage.

Much information on various forms of dynamometers will be found in *Trans.* A.S.M.E., vols. vii to xv inclusive, indexed under Dynamometers.

# ELECTRIC MOTORS AND THEIR CONTROL

By M. N. Halberg

## DEFINITIONS

**ALTERNATING CURRENT.**—An electric current, the direction of which reverses at regularly recurring intervals. Unless distinctly otherwise specified, *alternating current* refers to a periodically varying current with successive half waves of the same shape and area. Abbreviation, A.C.

**APPARENT EFFICIENCY** of an alternating-current motor is the product of its efficiency and its power factor.

**APPARENT POWER OR VOLT-AMPERES** in an alternating-current circuit is the product (r.m.s. value * of voltage across the circuit) × (r.m.s. value * of current in the circuit). Apparent power also is expressed in kilo-volt-amperes (1000 volt-amperes). Abbreviation, kva.

**ARMATURE.**—The part of a dynamo-electric machine which includes the main current-carrying winding. In direct-current machines and in alternating-current commutator machines, the armature winding is connected to the commutator, and the armature is the rotating member. In alternating-current machines without commutators the armature may be either the rotating member or the stationary member.

**ASYNCHRONOUS MACHINE.**—A dynamo-electric machine in which the speed of operation is not exactly proportional to the frequency of the system to which it is connected.

**AUTOMATIC TRIP.**—The opening (other than manually) of an oil or air circuit breaker as a result of changes in current or voltage, or of other electrical conditions.

**AUTO-TRANSFORMER.**—A form of transformer that has one continuous winding, part of which is common to both primary and secondary circuits.

**BRANCH CIRCUIT.**—That portion of a wiring system extending beyond the final automatic overload protective device of the circuit.

**CAPACITOR (Static Condenser).**—A device whose primary purpose is to store electric charges. It commonly is used in A.C. circuits to change the relative time phase between voltage applied and current flowing in the circuit. The usual form consists of two conducting plates, usually of aluminum foil, separated by a thin layer of insulation (dielectric), the combination being hermetically sealed in a steel container.

**CIRCUIT BREAKER.**—A device designed to open, under abnormal conditions, a current-carrying circuit without injury to itself. The term as used in the National Electrical Code applies only to the automatic type designed to trip on a predetermined overload of current.

**CIRCULAR MIL.**—The area of a circle of 1 mil diameter, or $(\pi/4) \times (0.001)^2$ sq. in. $= 0.000\,000\,7854$ sq. in.

**CLASS A INSULATION** consists of cotton, silk, paper and similar organic materials when impregnated or immersed in oil; also enamel as applied to conductors.

**CLASS B INSULATION** consists of inorganic materials, such as mica and asbestos in built-up form, combined with binding substances. If Class A material is used in small quantities in conjunction with Class B, for structural purposes only, the combined material may be considered as Class B, provided the electrical and mechanical properties of the insulated winding are not impaired by the application of the temperature permitted for Class B material. (The word "impair" is here used in the sense of causing any change which could disqualify the insulating material for continuous service.)

**CLASS C INSULATION** consists of inorganic materials such as pure mica, porcelain, quartz, etc.

**CLASS O INSULATION** consists of cotton, silk, paper and similar organic materials when neither impregnated nor oil immersed.

**COMMUTATING POLE (Interpole).**—An auxiliary pole placed between the main poles of a commutating dynamo-electric machine. Its exciting winding carries a current proportional to the load current and produces a flux in such a direction and phase as to assist the reversal of current in the short-circuited coil.

---

* R.m.s. value (root-mean-square) of a current or voltage is the value read by an ordinary ammeter or voltmeter. It numerically is equal to $\sqrt{\text{mean of (instantaneous values)}^2}$.

**COMMUTATOR.**—An annular ring or disc assembly of conducting members, individually insulated in a supporting structure, with an exposed surface for contact with current collecting brushes, and ready for mounting on an armature spider, shaft, or quill.

**CONDUCTOR.**—A metallic structure used to carry electric current. It usually is a wire or a combination of wires not insulated from one another, but bars or tubes also are used as conductors.

**CONTROLLER.**—A device, or group of devices, which governs, in some predetermined manner, the electric power delivered to the apparatus to which it is connected.

**CONVENTIONAL EFFICIENCY.**—The efficiency as computed by means of the component losses, most of which are accurately determinable, and the remainder of which are assigned conventional values; or all of the losses may be determined by conventional methods of test. The efficiency so determined is the ratio $O/(O + L)$ or the ratio $(I - L)/I$, where $O$ = output; $I$ = input; $L$ = losses.

**COUNTER ELECTROMOTIVE FORCE.**—The effective electromotive force, within a system, which opposes the passage of current in a specified direction.

**DIRECT CURRENT.**—A uni-directional current. As ordinarily used, the term designates a practically non-pulsating current. Abbreviation, D.C.

**EFFICIENCY** of an apparatus (machine or motor) is the ratio of the useful power output to the total power input.

**ELECTRICAL DEGREE.**—The 360th part of the angle subtended, at the axis of the machine, by two consecutive field poles of like polarity. One *mechanical degree* is thus equal to as many electrical degrees as there are pairs of poles in the machine.

**ELECTROMOTIVE FORCE.**—The property of a physical device which tends to produce an electric current in a circuit. Abbreviation, e.m.f.

**EXCITER.**—An auxiliary generator which supplies electric current to excite the field of another electrical machine.

**FREQUENCY, of an Alternating Current.**—The number of cycles through which the current passes per second; frequency is the reciprocal of the *period*.

**GENERATOR, Double Current.**—A machine which supplies both direct and alternating currents from the same armature.

**GENERATOR, Electric.**—A machine which transforms mechanical energy to electrical energy.

**GENERATOR, Induction.**—An induction machine (see below) driven above synchronous speed by an external source of mechanical power, and returning energy to the circuit.

**GENERATOR, Magneto-electric.**—An electric generator, the field poles of which are permanent magnets.

**GROUND.**—A conducting connection, whether intentional or accidental, between an electrical circuit and earth or any other conducting or partly conducting structure or material.

**INDUCTION MACHINE.**—An asynchronous alternating-current machine which comprises a magnetic circuit interlinked with two electric circuits, rotating with respect to each other and in which power is transferred from one circuit to another by electromagnetic induction. Examples of induction machines are induction motors, induction generators, and certain types of frequency converters and phase converters.

**KILOWATT.**—A unit of electrical power equal to 1000 watts or 1.34 horsepower.

**KILOWATT-HOUR.**—The work performed by one kilowatt acting for one hour.

**LOAD FACTOR.**—The ratio of the average load over a designated period to the peak load occurring in that period.

**MAGNETIC CONTROLLER.**—A controller all of whose basic functions are performed by electromagnets.

**MANUAL CONTROLLER.**—A controller all of whose basic functions are performed by hand.

**MOTOR, Adjustable Speed.**—See pp. 25–12, 25–32, 25–45.

**MOTOR, Capacitor.**—See p. 25–19.

**MOTOR, Capacitor-start.**—See p. 25–19.

**MOTOR, Compound-wound.**—A direct-current motor with two separate field windings connected, *a*, in parallel with the armature circuit, and, *b*, in series with the armature circuit. Winding *a* usually is the predominant field.

**MOTOR, Constant-speed.**—See p. 25–12.

**MOTOR, General Purpose.**—Any motor of 200 Hp. or less, and 450 r.p.m. or more having a continuous rating, and designed, listed or offered in standard ratings for use without restriction to a particular application.

**MOTOR, Induction.**—An induction machine that converts electrical energy delivered to the primary circuit into mechanical energy by the electromagnetic interaction between the primary and secondary circuits. The secondary circuit is short-circuited or closed through a suitable circuit.

**MOTOR, Large Power (Integral Horsepower).**—A motor built in a frame having a continuous rating of 1 Hp., open type, at 1700–1800 r.p.m., or in a larger frame.

**MOTOR, Non-excited Synchronous.**—A synchronous motor without a direct-current field winding.

**MOTOR, Reactor-start.**—A form of split-phase motor (see below) designed to start with a reactor in series with the main winding. The reactor is short-circuited, or otherwise made ineffective, and the auxiliary circuit is opened when the motor has attained a predetermined speed.

**MOTOR, Repulsion.**—A single-phase alternating-current motor with a stator winding arranged for connection to the source of supply, and a rotor winding connected to a commutator. Brushes on the commutator are short-circuited and so set that the line connecting the positive and negative brushes is at an angle to the neutral axis of the stator winding. This type of motor has a varying speed characteristic.

**MOTOR, Repulsion Induction.**—A form of repulsion motor which has a squirrel-cage winding in the rotor, in addition to the repulsion motor winding. This type of motor may have constant speed or varying speed characteristics. See p. 25–19.

**MOTOR, Repulsion-start Induction.**—A single-phase motor having the same windings as a repulsion motor, but in which, at a predetermined speed, the rotor winding is short-circuited or otherwise connected to give the equivalent of a squirrel-cage winding. This type of motor starts as a repulsion motor, but operates as an induction motor with constant speed characteristics. See p. 25–19.

**MOTOR, Resistance-start.**—A form of split-phase motor (see below) with a resistance connected in series with the auxiliary winding. The auxiliary circuit is opened when the motor has attained a predetermined speed.

**MOTOR, Series-wound.**—A commutator motor in which the field circuit and armature circuit are connected in series.

**MOTOR, Shaded Pole.**—See p. 25–19.

**MOTOR, Shunt-wound.**—A direct-current motor in which the field circuit and armature circuit are connected in parallel.

**MOTOR, Slip-Ring.**—See Motor, wound-rotor induction.

**MOTOR, Small Power (Fractional Horsepower).**—A motor built in a frame smaller than that having a continuous rating of 1 Hp., open type, at 1700–1800 r.p.m.

**MOTOR, Special Purpose.**—An industrial power motor specifically designated and listed for a particular power application, where load requirements and duty cycle are definitely known.

**MOTOR, Split-phase.**—A single-phase induction motor equipped with an auxiliary winding, which is displaced in magnetic position from, and connected in parallel with, the main winding. The auxiliary circuit is opened when the motor has attained a predetermined speed. See p. 25–19.

Note: The term split-phase motor, used without qualification describes a motor to be used without impedance, other than that offered by the motor windings themselves.

**MOTOR, Squirrel-cage Induction.**—An induction motor in which the secondary circuit consists of conductors suitably disposed in slots in the secondary core. See p. 25–28.

**MOTOR, Synchronous.**—A synchronous machine which transforms A.C. electrical power to mechanical power, and which has a speed strictly proportional to the frequency of the operating current. See p. 25–20.

**MOTOR, Synchronous Induction.**—A wound-rotor induction motor to which direct-current excitation is supplied when it approaches rated speed, enabling it to start as an induction motor and operate as a synchronous motor. See p. 25–40.

**MOTOR, Universal.**—A series-wound or compensated series-wound motor which may be operated either on direct current or single-phase alternating current (of approximately the same voltage and a frequency not greater than 60 cycles per second) at approximately the same speed and output. See p. 25–20.

**MOTOR, Wound-rotor Induction.**—An induction motor in which the secondary circuit consists of a polyphase winding, or coils whose terminals are short-circuited or closed through suitable circuits. (When provided with collector or slip rings a wound-rotor induction motor also is known as a slip-ring induction motor). See p. 25–30.

**OPEN MACHINE (or Motor).**—A self-ventilated machine having no restriction to ventilation, other than that necessitated by mechanical construction.

**POWER.**—The rate of transfer of energy. In the case of an alternating-current circuit the word power is generally used to denote the average value of the power over a cycle. The power in an electric circuit at any instant is equal to the product of the values of the current and voltage at that instant, and generally is called instantaneous power.

**POWER FACTOR.**—The ratio of the power to the apparent power, that is, it equals kw./kva. The maximum power factor is 1 or unity. It may be lagging or leading, depending upon whether the current wave lags or leads the voltage wave. See Kent's Mechanical Engineers' Handbook—Power, pp. 15–53 to 15–60, forming Volume 2 of this series.

**PROOF (as a suffix).**—A machine (or apparatus) is designated as splash-proof, moisture-proof, explosion-proof, etc., when so constructed, protected or treated that subjection to the specified material or condition will not interfere with its successful operation.

**RATING of a machine, apparatus or device.**—A designated limit of operating characteristics based on definite conditions. Such operating characteristics as load, voltage, frequency, etc., may be given in the rating.

**RATING, Continuous.**—The rating that defines the load which can be carried for an indefinitely long time.

**RATING, Short-time.**—The rating that defines the load which can be carried for a short and definitely specified time, the machine, apparatus or device being at approximately room temperature at the time load is applied.

**RESISTING (as a suffix).**—A machine (or apparatus) is designated as moisture-resisting, fume-resisting, etc., when so constructed, protected or treated that it will not be readily injured when subjected to the specified material.

**SEMI-MAGNETIC CONTROLLER.**—A controller having part of its basic functions performed by electromagnets and part by other means.

**SINGLE-PHASE CIRCUIT.**—A circuit energized by a single alternating electromotive force. (A single-phase circuit usually comprises two wires. The currents in these two wires, counted outwards from the source, differ in phase by 180 degrees or a half cycle.)

**SLIP (of an induction machine).**—The ratio, expressed as a percentage, of the difference between operating speed and synchronous speed to the synchronous speed.

**SWITCH, General Use.**—A switch intended for use as a switch in general distribution and branch circuits. It is rated in amperes and is capable of interrupting its rated current at its rated voltage.

**SWITCH, Isolating.**—A switch intended for isolating a circuit from its source of power. It is to be operated only when the circuit has been opened by some other means.

**SWITCH, Motor-circuit.**—A switch intended for use in a motor-branch-circuit. It is rated in horsepower and is capable of interrupting the maximum operating overload current of a motor of the same horsepower at the rated voltage. The maximum operating overload of A.C. motors is six times the rated current, and of D.C. motors is four times the rated current.

**SYNCHRONOUS MACHINE.**—A dynamo-electric machine in which the speed of normal operation is exactly proportional to the frequency of the current.

**THREE-PHASE CIRCUIT.**—A combination of circuits energized by alternating electromotive forces which differ in phase by one-third of a cycle, *i.e.*, 120 degrees.

**TIGHT (as a suffix).**—A machine is designated as water-tight, dust-tight, etc., when so constructed that the enclosing case will exclude the specified material.

**TORQUE.**—See p. 25–14.

**TWO-PHASE CIRCUIT.**—A combination of circuits energized by alternating electromotive forces which differ in phase by a quarter of a cycle; *i.e.*, 90 degrees.

**UNDER-VOLTAGE PROTECTION.**—The effect of a device, operative on the reduction or failure of voltage, to cause and maintain the interruption of power to the main circuit.

**UNDER-VOLTAGE PROTECTION, Time Delay.**—The effect of a device, operative on the reduction or failure of voltage for a definite period of time, to cause and maintain the interruption of power to the main circuit.

**UNDER-VOLTAGE RELEASE.**—The effect of a device, operative on the reduction or failure of voltage, to cause the interruption of power to the main circuit, but not to prevent the re-establishment of the main circuit on return of voltage.

## APPLICATION OF MOTORS AND CONTROL

**FACTORS AFFECTING MOTOR SELECTION.**—The various factors which may require consideration in selecting a motor and controller for a given application are summarized and discussed on pp. 25–07 to 25–10. These are broadly classified in accordance with their relation to: *a*. The power supply; *b*. The driven machine; *c*. The location.

**Power Supply**

- Characteristics
  - D.C.—voltage
  - A.C.—voltage, phases and frequency
- Power rates
  - Energy charge
  - Power-factor clause
  - Demand charge
- Voltage regulation
  - Starting current limitations
  - Allowable current pulsations
- Continuity of power
- Short-circuit current
- Voltage surges

**Driven Machine**

- Mechanical arrangement
  - Horizontal or vertical shaft
  - Tilting
  - Stationary or portable
  - Method of connecting motor — Direct-connected, built-in, belt, chain, or gear drive
  - Space available
- Speed, speed range, regulation
- Direction of rotation, reversing
- Horsepower, r.m.s., peak
- Torques
  - Starting, breakaway, pull-in
  - Running-torque pulsations
- $WR^2$ of rotating parts
- Thrust
- Frequency of starting
- Deceleration time
- Operating schedule
- Initiation of operating sequence

**Location**

- Ambient temperatures
- Altitude
- Moisture
- Dirt
- Corrosive atmosphere
- Explosive dust or gas
- Effect of noise
- Codes and ordinances

## Power Supply

**VOLTAGE** of a D.C. power supply, and the voltage, number of phases, and frequency of an A.C. power supply must be known in order to select a correspondingly rated motor and controller. In most cases these conditions are fixed and readily determined. However, in some cases a choice is available or a conversion from one set of conditions to another is desirable. For example, it often is necessary to convert a high A.C. voltage to a lower value by means of transformers for economical use of small motors. Again, in some applications, as those involving operation over a wide speed range or severe reversing duty, it is desirable to convert A.C. to D.C., by means of a motor-generator set or a rectifier, to allow the use of D.C. motors.

**POWER RATES** may affect the choice of motor and controller, since the efficiencies of various types of motor differ appreciably, which means a corresponding difference in the power used. This is particularly true, in the case of adjustable speed motors where wide variations in efficiency occur, which must be balanced against wide differences in cost. Many A.C. power-rate schedules incorporate a *power-factor clause*, by which the billing is adjusted in accordance with the power-factor of the current used. This may affect the choice of motor. For example, it may justify the use of a synchronous motor where an induction motor otherwise would be selected. Finally, most rate schedules embody a *demand charge*, that is, the maximum rate at which energy is used for a given period of time, as well as the total amount consumed, determines the power bill. This makes it desirable to maintain as uniform a load as possible at all times, which in some applications will justify the use of an adjustable speed or multi-speed motor instead of a constant speed machine. See Purchased Power, pp. 15–03 to 15–20, and Power Factor, pp. 15–53 to 15–60, Kent's Mechanical Engineers' Handbook—Power, forming Vol. 2 of this series.

**VOLTAGE REGULATION** of the power supply represents the drop in voltage which occurs with a certain increase in the current drawn. This must be considered, first, because the torques developed by motors vary with the impressed voltage, so that the actual voltage at the motor terminals under the various operating conditions must be known. In the case of A.C. motors, the starting torques vary as the square of the voltage. Since these motors draw a relatively high starting current, the effect of the voltage regulation of the power supply is particularly important. Secondly, if lights are supplied from the same power circuit, a drop in voltage of about 2% causes a noticeable flicker of these lights. Finally, a drop in voltage of 30% or more may cause other motors on the system to stall or be disconnected from the line by their under-voltage protective device.

Power companies usually establish limits to the starting current which can be drawn from the line by motors, in order to prevent excessive drop in line voltage. These factors often necessitate the use of reduced-voltage controllers, where full-voltage starting otherwise would be acceptable. In some cases, a different type of motor must be used, for example, a wound-rotor induction motor instead of a squirrel-cage induction motor, in order to obtain sufficient starting torque while keeping within the allowable starting current.

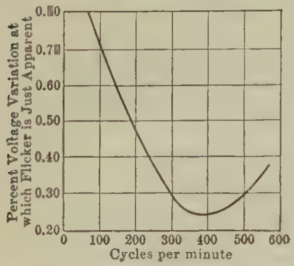

Fig. 1. Voltage Variation Causing Light Flicker at Various Temperatures

**Pulsating Current.**—Where the load is such that the motor draws a pulsating current from the line, corresponding variations in line voltage occur. If these have a frequency lying in a certain range (see Fig. 1), they can be of very small magnitude and yet produce a noticeable flickering of lights supplied from the circuit. The usual limit established for current pulsation is 66% of motor full-load current. In most cases this does not cause light flicker, but in particular installations the regulation of the system may be such as to require a much lower limit of pulsation such as 30 or 40%.

**CONTINUITY OF POWER SUPPLY** may affect the choice of motors and control. Thus, if momentary interruptions or *dips* in line voltage are apt to occur, the use of time-delay rather than instantaneous under-voltage protection may be justified. See p. 25–52. In special cases, control equipment may be required which automatically will transfer the motor from one source of power to another, in the event of failure of the first.

**SHORT-CIRCUIT CURRENT** of the power system may affect the choice of control equipment. If the line switch of the controller is to be called upon to interrupt short-circuit current, it may be necessary to use a circuit-breaker of suitable rating, or a high-interrupting-capacity contactor, to meet the requirements.

**VOLTAGE SURGES.**—When a motor is supplied from high-voltage overhead power lines, lightning disturbances in the surrounding area may produce dangerous voltage surges at the motor terminals. Special winding insulation and in some cases external protective equipment may be justified.

## Driven Machine

**MECHANICAL ARRANGEMENT** of the driven machine is the first consideration. Whether it is driven through a horizontal shaft or a vertical shaft determines which of these two types of motor should be selected. In some cases the motor normally operates in one position, but may, momentarily or for extended periods, be tilted in one or more directions. This condition may require special bearing construction to carry the thrust and prevent leakage of lubricant. Again, the motor may be required to operate continuously in any position. This usually means the use of grease-lubricated ball bearings.

Whether the driven machine is *stationary* or *portable* may affect the choice of motor. In the latter case, compactness and light weight are often essential. Operation in more than one position usually is involved.

**Method of Connecting Motor** to the driven machine must be considered. If the speed corresponds to that of an economical motor speed, a direct-connected motor normally would be used. Otherwise, speed transformation by belt, chain or gears must be employed. Maintenance, efficiency, and space requirements as well as initial cost enter into this choice. In some cases a direct-connected motor economically may be *built-in*. This usually involves the use of a special motor, supplied without shaft or bearings, and arranged to be mounted on the shaft of the driven machine. In some cases, the motor stator also is arranged to be supported from the driven machine. Compactness is one of the principal advantages of this construction. Where the motor drives through a flat belt, multiple-V belt, or chain, the dimensions of pulleys or sprockets and the center distance must be known, in order to determine the side pull on the motor shaft. In some cases, the motor must have an extended shaft and outboard bearing to limit bearing pressure and shaft deflection. A sliding base, or other means for adjusting the position of the motor, to maintain proper tension in the driving member is necessary with belt or chain drive.

**Space Available** for a motor may affect its choice. If space is limited, a direct-connected or built-in motor usually is most suitable. Where the speed of the driven machine prohibits this choice, a gear-motor often is the best solution. In some cases forced ventilation of a motor by an external blower may be used effectively to reduce the motor size. Similar results may be obtained by using a motor with Class B insulation, operating at a correspondingly higher temperature rise.

**SPEEDS.**—The operating speed, speeds, or speed range of the driven machine must be known in order to select a corresponding single-speed, multi-speed, or adjustable speed motor. If the machine operates at a single speed, any type of motor may be used, the choice being made on other factors. Where two, three or four fixed speeds, bearing the proper ratio to each other, are acceptable, a multi-speed squirrel-cage induction motor may meet the requirements. Where the speed range does not exceed 2:1, and a reasonable number of speed points is satisfactory, and where considerable variation in speed with load is not detrimental, the wound-rotor induction motor should be considered. For more severe requirements a D.C. motor with field or variable-voltage control, or an A.C. adjustable-speed, brush-shifting motor may be necessary.

**Speed Regulation.**—The allowable speed regulation (variation in speed with load) may determine the type of motor, particularly where adjustable speed operation is involved. For most single-speed applications, the squirrel-cage induction motor or shunt-wound D.C. motor is satisfactory, but in a few applications zero speed regulation is required. This necessitates the use of a synchronous motor. For adjustable speed service, the wound-rotor induction motor, and the D.C. motor with armature resistance control, often are eliminated because of their high speed regulation.

**DIRECTION OF ROTATION.**—Certain types of motors require adjustment or reconnection of windings to change the direction of rotation, which can be most conveniently done in the factory. Hence, the direction of rotation should be specified. Where the motor is to run in both directions, a motor suitable for reversing, and a reversing controller, must be provided.

**HORSEPOWER** required to drive the load determines the motor rating. Where the load is not constant but varies with time, the complete duty cycle (Hp. *vs.* time curve) should be obtained. From this curve, the peak horsepower, which determines the maximum torque of motor, and the root-mean-square (r.m.s.) horsepower can be calculated. The latter is the square root of the mean value (averaged against time) of the square of the horsepower needed. It is an approximate indication of the horsepower rating of the driving motor required from the standpoint of heating. However, where large variations in load occur, or where the motor is shut down, accelerating or decelerating an appreciable portion of the time, the r.m.s. horsepower does not necessarily give a true indication of the equivalent continuous load, and it is advisable to consult the motor manufacturer. If the load continues at a certain value for an extended period of time (15 minutes to 2 hours, depending on the size of the motor), the horsepower rating of the motor should be not less than this value, regardless of any subsequent reduction in load. Where the motor operates at more than one speed, the horsepower required at each speed must, of course, be known.

**TORQUES** necessary to start and drive a load deserve careful consideration. Of particular importance is the breakaway torque requirement, since this often is considerably higher than the running torque. Furthermore, reduced-voltage starting may be necessary to meet starting current limitations, which reduces the torque delivered by the motor. Where a synchronous motor is being considered, the torque required at full speed under starting conditions is equally important, since it determines the pull-in torque. Pull-in torque is not necessarily equal to full-load torque, since the machine may be unloaded for starting, or may be required to start when the load is temporarily higher than normal. It is often desirable or essential to know the load torque at all speeds from standstill to full speed (speed-torque curve). This affects the accelerating time and hence the heating of the motor and control equipment. In particular, squirrel-cage induction motors, synchronous motors, and starting resistors, reactors, and auto-transformers may have to be of special design if the accelerating time is unusually long. Where reduced-voltage starting is employed, the speed-torque curve of the load determines the speed to which the motor will accelerate on reduced voltage, and hence determines the current inrush when the motor is transferred to full voltage.

**Running Torque.**—The horsepower required and the speed of the driven machine determine the running torque. Certain driven machines, of which reciprocating compressors are typical, have a load torque which pulsates periodically. To prevent excessive pulsation in the current drawn by the motor proper, fly-wheel effect, $WR^2$, must be provided in the motor or driven machine. In the case of synchronous motor drives, the fly-wheel effect must be such that the natural frequency of the motor is not close to the frequency of any impulses in the load torque. The former can be calculated as follows: Let $F$ = natural frequency of motor, cycles per min.; $WR^2$ = (weight, lb.) × (radius of gyration, ft.)$^2$ of the rotating parts of motor and load; $N.$ = rev. per min. of motor;

$f$ = line frequency; $P_r$ = synchronizing power of motor, kilowatts per electrical radian. Then $F = (35{,}200/N)\sqrt{(P_r \times f)/WR^2}$

**$WR^2$ OF THE ROTATING PARTS** of the driven machine affects the accelerating time, and hence affects the heating during the starting period of motors and control equipment. Its value is particularly important where the motor is started frequently, or where reversing duty is involved. The $WR^2$ always should be known if a synchronous motor is to be employed, since the pull-in torque of the motor varies approximately as the square root of the total $WR^2$ of motor and load. If a rotating member of the driven machine operates at a different speed from that of the motor, its $WR^2$ can be converted to an equivalent value at the motor shaft by multiplying by

$$\{(\text{r.p.m. of rotating member})/(\text{r.p.m. of motor})\}^2$$

**THRUST.**—Some driven machines (certain types of pumps and fans are typical) impose a thrust on the motor in a direction parallel to the shaft. Horizontal motors with thrust bearings may be required. Vertical motors may need an over-size thrust bearing if considerable external thrust is imposed.

**FREQUENCY OF STARTING** may affect the choice of motor and controller, since each start results in additional heating of the motor windings, starting resistors, etc. This must be considered in connection with the load torques and load $WR^2$, which determine the accelerating time and hence the heating during each start.

In some applications, **rapid deceleration** of the motor and load is essential. Where induction motors are used, it may be necessary to provide *plugging control*, and with synchronous or D.C. motors, dynamic braking control (see p. 25–58.)

**Plugging** consists of reversing two leads of a motor while the motor is running, so as to reverse the phase rotation. The control thus is similar to that provided for reversing service. A relay, mounted on the motor shaft, usually is included to disconnect the motor from the line when it stops, and prevent it from starting in the reverse direction.

**THE OPERATING SCHEDULE,** *i.e.*, the total number of hours of operation per year, of a machine should be known. Where this figure is high, motors having maximum efficiency are more readily justified. Where the load or speed varies, the operating time under each condition should be considered to permit proper evaluation of the motor characteristics to be made.

**Initiating Operating Sequence.**—If it is acceptable for the operator to start and stop the motor at the controller, the latter may be of the manual type. Where remote control or automatic operation in response to temperature, pressure, liquid level, etc., is required, a magnetic controller must be used.

### Location

**THE AMBIENT TEMPERATURE,** if above 40° C., and the **altitude,** if greater than 3300 ft. above sea level may affect the choice of motor. See p. 25–11. If a motor is to operate in a very moist atmosphere special insulation or, under severe conditions, totally-enclosed or enclosed-separately-ventilated construction may be required. Extreme conditions of dirt or corrosive atmospheres also require the use of totally-enclosed or enclosed-separately-ventilated motors. If located where explosive dust (Class II Group G), or gases (Class I, Group D), may be present, a corresponding type of explosion-proof motor should be selected.

**Noise.**—Installations in public buildings, as schools, theatres, hospitals, stores, etc., and residences, unless isolated from occupied sections, may require quiet operating motors to prevent objectionable noise. Suitable resilient mountings to prevent transmission of vibration through the building structure are often necessary. Finally, local regulations such as codes and ordinances must be considered. Some require special enclosures on motors and control equipment to reduce the hazard to operators.

# ELECTRIC MOTORS

## 1. GENERAL

**POWER SUPPLY.**—Practically all public utility power systems distribute alternating-current (A.C.) power, although direct-current (D.C.) power is provided in the downtown areas of certain large cities. A.C. motors are, in general, less costly, require less maintenance than D.C. machines, and meet the requirements of the large majority of applications. However, for certain loads D.C. motors have more suitable characteristics, and are used, even though A.C. to D.C. conversion equipment is required. D.C. motors must be designed for the proper line voltage, and A.C. motors for the proper voltage, phase, and frequency.

**Standard Motor Voltages** are as follows: Direct-current, 32, 115, 230, 550 volts. Alternating-current, 110, 220, 440, 550, 2200, 4000, 6600, 11,000, 13,200 volts. Since alternating current can be transformed readily from one voltage to another, a choice of motor voltage often is available. In general, the lowest cost and best operating characteristics are obtained with a voltage increasing with the horsepower rating as indicated in Table 1. Certain types of motors are available with a *dual voltage* feature, *i.e.*, additional terminals are provided so the motors can be connected for either one of two voltages, as 110 and 220 volts, or 220 and 440 volts.

**Frequency.**—Alternating-current frequencies of 60 and 25 cycles are standard in the U. S. The latter, primarily because of the limitations it imposes on the selection of motor speeds and its inferiority for lighting, is rapidly (1937) being superseded by the former. Frequencies of 50, 40 and 30 cycles also are in use in certain sections of the U. S., but are being superseded by 60 cycles. In Europe and European dependencies, 50 cycles is the general standard. In Canada, except for parts of Ontario, 60 cycles is standard.

**Phase.**—Single-phase, three-phase, and, to a limited extent, two-phase power is distributed and used commercially in the U. S. Three-phase energy is most satisfactory for power purposes, and is the accepted standard. In general, single-phase motors cost more and have less satisfactory operating characteristics than three-phase machines. However, single-phase power is used for lighting, and in residential and rural districts often is the only power available. Hence, single-phase motors commonly are used on household appliances and other small equipment to be installed in such districts. Power companies place a limit on the size of motor which may be connected to single-phase lines. This limit usually falls between $^{1}/_{4}$ and $^{3}/_{4}$ Hp. for 110-volt circuits and between 3 and 10 Hp. for 220-volt circuits.

**HORSEPOWER RATING.**—Motors usually are rated in horsepower, the rating representing their power output. Very small motors ($^{1}/_{60}$ Hp. and below) usually are rated in watts output (746 watts = 1 Hp.). Standard ratings have been established for the various types of motors.

Most motors are rated on a continuous basis, that is, they will carry rated load continuously. However, many types, such as crane and hoist motors, are given short time ratings such as 15-min., $^{1}/_{2}$-hr., or 1-hr. ratings, indicating that they can carry their rated load for the designated period of time, after which they must be allowed to cool to room temperature. In some cases a motor is given several different ratings, each for a different period of time. Short-time-rated motors are used on intermittent loads, the time rating being chosen to give the motor heating equivalent to that produced by the actual duty cycle of the load.

**TEMPERATURE RISE.**—Motors are designated 40-deg., 50-deg., etc., indicating the temperature rise in deg. C. that will not be exceeded when the motor carries rated load continuously (or for a specified time in the case of short-time-rated motors). The temperature rise refers to the windings, core and other parts adjacent to the insulation. Some motors are given different temperature guarantees for different parts as armature, field, etc. Temperatures usually are determined by thermometer, although temperature detectors embedded in the winding are used on large motors. In some cases, the temperature rise of a winding is determined by measuring the change in its resistance.

Temperature rise guarantees usually are on the basis of normal conditions of ventilation, an altitude of not more than 1000 meters (3300 ft.), and an ambient temperature of 40 deg. C. Less effective dissipation of heat at higher altitudes (a result of reduced density of air) causes a higher temperature rise. It is assumed that the temperature rise as measured at altitudes below 3300 ft. is 1% less than the temperature rise at a higher altitude for each 330 ft. by which this altitude exceeds 3300 ft. Expressed as an equation this becomes,

$$t_h = t_s/\{1.1 - (h/33{,}000)\} \quad . \; . \; . \; . \; . \; . \; . \; . \; . \quad [1]$$

where $t_h$ = temperature rise at altitude $h$, $t_s$ = temperature rise at sea level, $h$ = altitude, ft. Thus a motor having a temperature rise of 40° C. at sea level, will have at an altitude of 9900 ft. a temperature rise of

$$t_h = 40/\{1.1 - (9900/33{,}000)\} = 50^\circ \text{ C.}$$

The type of insulation used has an important bearing on the allowable temperature

**Table 1.—Recommended Voltage Ratings of A.C. Motors**

| Motor Horsepower | Recommended Voltage | Motor Horsepower | Recommended Voltage |
|---|---|---|---|
| 3/4 and smaller | 110*, 220* | 50–200 | 220, 440*, 550, 2200* |
| 1–5 | 110, 220*, 440*, 550 | 200–500 | 440*, 550, 2200* |
| 5–50 | 220*, 440*, 550 | 500–1000 | 2200*, 4000, 6600 |

* Preferred voltage ratings.

rise. For Class A insulation (see p. 25–03) the upper temperature limit is placed at 105° C. If the insulation is allowed to reach a higher temperature unduly rapid deterioration is expected. For Class B insulation the upper temperature limit is placed at 125° C. Class A insulation is standard for most types of motors, although Class B insulation usually can be obtained at increased cost. Since it is impractical to measure the temperature of a motor at the *hottest spot*, standard practice limits the temperature as measured to a lower value. Where the temperature is measured by thermometer, it is assumed that the thermometer reading will be 15° C. below the hottest spot temperature. (For totally enclosed motors the differential is taken as 10° C.) Where temperature detectors are used the differential is taken as 5° C.; with the resistance method of temperature determination the differential usually is taken as 10° C. On this basis the temperature limits and temperature rises (based on 40° C. ambient) are as indicated in Table 2. Where a motor is to operate in an ambient temperature in excess of 40° C. a motor should be chosen with a temperature rise correspondingly lower.

Many types of motors are rated on the basis of a temperature rise less than allowable for the type of insulation employed. For example, 40° C. rise by thermometer is a common rating for motors with Class A insulation, whereas in a 40° C. ambient temperature, a rise of 50° C. is allowable. Such motors are frequently guaranteed to have a certain overload capacity, which is not available in motors rated at the maximum allowable temperature. Temperatures and temperature rises usually are given in degrees Centigrade. For conversion of Centigrade to Fahrenheit and Fahrenheit to Centigrade, see p. 28–50.

**SPEED CHARACTERISTICS.**—All motors may be classified, according to their speed characteristics, as follows: *a.* Constant speed. *b.* Varying speed. *c.* Adjustable speed. *d.* Adjustable varying speed. *e.* Multi-speed.

**A Constant Speed Motor** is one in which the speed is practically constant regardless of load. A change of a few percent in speed between no load and full load is characteristic, except with synchronous motors. Induction motors with small slip, and D.C. shunt motors are constant speed machines.

**A Varying Speed Motor** is one in which speed varies with load, ordinarily decreasing as load increases. The series D.C. motor and the high-slip, squirrel-cage induction motor are typical.

**An Adjustable Speed Motor** is one the speed of which can be varied gradually over a considerable range, but when once adjusted, remains practically constant being unaffected by load. The D.C. shunt-wound motor with field resistance control, designed for a considerable range of speed adjustment, is an example of this type of motor.

**An Adjustable Varying Speed Motor** is one in which the speed can be varied gradually over a considerable range, but in which the speed, when once adjusted to a given load, will vary in considerable degree with change in load; for example, a wound-rotor induction motor with secondary resistance control.

**A Multi-speed Motor** is one which can be operated at any one of several definite speeds, each being practically independent of the load; an induction motor with a primary winding capable of various pole groupings is an example.

**Operating Speeds.**—A characteristic of all constant-speed A.C. motors is that their operating speed is equal to or slightly less than one of the *synchronous speeds* corresponding to the frequency of the power supply (see Table 3). Multi-speed A.C. motors operate at two or more of these speeds. Synchronous motors, as their name implies, operate at exact synchronous speed. Induction motors operate at synchronous speed under no load, but under load they operate at a slightly lower speed. The difference between synchronous speed and full-load speed is known as full-load slip; it varies between 1 and 5% of synchronous speed for constant speed induction motors. D.C. motors can be designed

**Table 2.—General Temperature Limits for Motors**

| | Class A Insulation | Class B Insulation |
|---|---|---|
| **Measured by thermometer** | | |
| Temperature limit—open motors | 90° C. | 110° C. |
| " " —totally enclosed motors | 95° C. | 115° C. |
| Temperature rise (40° C. ambient)—open motors | 50° C. | 70° C. |
| " " ( " " )—totally enclosed motors | 55° C. | 75° C. |
| **Measured by temperature detectors** | | |
| Temperature limit | 100° C. | 120° C. |
| Temperature rise (40° C. ambient) | 60° C. | 80° C. |
| **Measured by resistance method** | | |
| Temperature limit | 95° C. | 115° C. |
| Temperature rise (40° C. ambient) | 55° C. | 75° C. |

for any required speed, subject to mechanical limitations. However, for the purpose of standardization, constant-speed D.C. motors usually are designed for full-load speeds approximately equal to the full-load speeds of 60-cycle induction motors.

In some cases, the speed classification of a motor depends entirely upon the control used with it. For example, a wound-rotor induction motor may be constant speed, varying speed or adjustable varying speed with no structural change in the motor whatsoever. A constant-speed D.C. motor may become, with no change in the motor itself, a wide-range adjustable-speed motor by the provision of means for varying the voltage impressed on its armature.

**DIRECTION OF ROTATION.**—Facing the end of the machine opposite the drive, the standard direction of rotation for all non-reversing motors, with the exception of polyphase induction motors, is counter clockwise. Unless otherwise specified standard motors are designed or connected for the standard direction of rotation. In the case of polyphase A.C. motors the terminals must be connected to the power lines in accordance with their phase rotation marking. This rule does not apply to polyphase induction motors whose terminals are not marked for any particular direction of rotation. They must be connected to the power lines and if the direction of rotation is wrong, two leads are reversed. Most motors can be reversed either by a change in connections or by mechanical adjustments.

**EFFICIENCY.**—The efficiency of a motor is defined as the ratio of useful power output to the total power input. Since power input is usually given in kilowatts,

$$\text{Efficiency} = (0.746 \times \text{Hp. output})/(\text{kilowatts input}),$$
$$\text{Kilowatts input} = (0.746 \times \text{Hp. output})/(\text{efficiency})$$

Motors of the same type and rating usually differ but little in efficiency. There may be considerable difference in the efficiency of motors of different types; this is particularly true of adjustable speed motors operating at reduced speeds. The efficiency of motors also varies considerably with the load and usually is highest at $^3/_4$ or full load. At light loads the efficiency is quite low.

**POWER-FACTOR.**—The power-factor of a motor is defined as the ratio of the kilowatts input to the kilovolt-amperes input where

$$\begin{aligned} \text{kva.} &= (\text{volts} \times \text{amperes})/1000, \text{ for single-phase motors,} \\ &= (1.73 \times \text{volts} \times \text{amperes})/1000, \text{ for 3-phase motors,} \\ &= (2 \times \text{volts} \times \text{amperes})/1000, \text{ for 2-phase motors.} \end{aligned}$$

Thus the kva. input to a motor equals (kw. input/power factor).

Table 3.—Synchronous Speeds Possible at Various Frequencies

| No. of Poles | 60 Cycles | 50 Cycles | 40 Cycles | 25 Cycles | No. of Poles | 60 Cycles | 50 Cycles | 40 Cycles |
|---|---|---|---|---|---|---|---|---|
| 2 | 3600 | 3000 | 2400 | 1500 | 52 | 138.5 | 115.4 | 92.3 |
| 4 | 1800 | 1500 | 1200 | 750 | 54 | 133.3 | 111.1 | 88.9 |
| 6 | 1200 | 1000 | 800 | 500 | 56 | 128.6 | 107.2 | 85.7 |
| 8 | 900 | 750 | 600 | 375 | 58 | 124.1 | 103.5 | 82.8 |
| 10 | 720 | 600 | 480 | 300 | 60 | 120 | 100 | 80 |
| 12 | 600 | 500 | 400 | 250 | 62 | 116.1 | 96.8 | 77.4 |
| 14 | 514.2 | 428.6 | 343 | 214.3 | 64 | 112.5 | 93.7 | 75 |
| 16 | 450 | 375 | 300 | 187.5 | 66 | 109 | 90.8 | 72.7 |
| 18 | 400 | 333.3 | 266.6 | 166.6 | 68 | 105.9 | 88.2 | 70.6 |
| 20 | 360 | 300 | 240 | 150 | 70 | 102.8 | 85.7 | .... |
| 22 | 327.2 | 272.7 | 218.1 | 136.3 | 72 | 100 | 83.3 | .... |
| 24 | 300 | 250 | 200 | 125 | 74 | 97.3 | 81 | .... |
| 26 | 277 | 230.8 | 184.5 | 115.4 | 76 | 94.7 | 78.9 | .... |
| 28 | 257.1 | 214.2 | 171.5 | 107.1 | 78 | 92.3 | 76.9 | .... |
| 30 | 240 | 200 | 160 | 100 | 80 | 90 | 75 | .... |
| 32 | 225 | 187.5 | 150 | 93.7 | 82 | 87.8 | 73.2 | .... |
| 34 | 212 | 176.5 | 141.1 | 88.2 | 84 | 85.7 | 71.4 | .... |
| 36 | 200 | 166.6 | 133.3 | 83.3 | 86 | 83.7 | ..... | .... |
| 38 | 189.5 | 157.9 | 126.3 | 78.9 | 88 | 81.8 | ..... | .... |
| 40 | 180 | 150 | 120 | 75 | 90 | 80 | ..... | .... |
| 42 | 171.5 | 142.8 | 114.2 | 71.4 | 92 | 78.3 | ..... | .... |
| 44 | 163.5 | 136.3 | 109 | ..... | 94 | 76.6 | ..... | .... |
| 46 | 156.6 | 130.5 | 104.3 | ..... | 96 | 75 | Lower speeds are limited by cost rather than by design. | |
| 48 | 150 | 125 | 100 | ..... | 98 | 73.5 | | |
| 50 | 144 | 120 | 96 | ..... | 100 | 72 | | |

D.C. motors and certain types of A.C. motors have a power factor of unity (100%); that is, kw. input = kva. input. However, the more common types of A.C. motors, such as the induction motor, have a *lagging* power factor of less than unity. For the effect of low power factor, and the means of improving it, see Kent's Mechanical Engineers' Handbook—Power, p. 15–53, forming Vol. 2 of this series.

The product of the efficiency and the power factor of a motor is the *apparent efficiency.* Thus

$$\text{kva. input} = \text{kw./P. F.} = (0.746\ \text{Hp.})/(E \times \text{P. F.}) = 0.746\ \text{Hp.}/E_a$$

where $E$ = efficiency; $E_a$ = apparent efficiency; P. F. = power factor.

**FULL-LOAD CURRENT.**—The full-load current of a motor is the current drawn from the line when the motor is carrying full load, with rated voltage and frequency (A.C. motors) applied. It may be calculated as follows, $I_{\text{max.}}$ being full-load current:

**D.C. Motors**

$$I_{\text{max.}} = (746 \times \text{Hp.})/(\text{Efficiency} \times \text{Voltage})$$

**Single-phase A.C. Motors**

$$I_{\text{max.}} = (746 \times \text{Hp.})/(\text{Efficiency} \times \text{Voltage} \times \text{Power Factor})$$

**Three-phase A.C. Motors**

$$I_{\text{max.}} = (746 \times \text{Hp.})/(1.73 \times \text{Efficiency} \times \text{Voltage} \times \text{Power Factor})$$

**Two-phase A.C. Motors, 4-wire** *

$$I_{\text{max.}} = (746 \times \text{Hp.})/(2 \times \text{Efficiency} \times \text{Voltage} \times \text{Power Factor}).$$

**TORQUES.**—The full-load torque of a motor is fixed by its horsepower and speed rating.

$$\text{Full-load torque in lb.-ft.} = 5250 \times \text{Hp./r.p.m.}$$

This is the basic torque of a motor. Other torques (see below) are often expressed as a percentage of full-load torque.

Other motor torques which are of importance are: *a.* Starting torque; *b.* Pull-up torque (A.C. motors); *c.* Breakdown torque (A.C. motors); *d.* Pull-in torque (synchronous motors); *e.* Pull-out torque (synchronous motors).

**Starting Torque** of a motor is the torque developed at zero speed. In A.C. motors, it is the minimum torque for all angular positions of the rotor, with rated voltage and frequency applied to the motor.

**Pull-up Torque** is the minimum torque developed by a motor during the period of acceleration from rest to full speed, with rated voltage and frequency applied to the motor. In some applications, the torque developed by a motor at all speed points from zero to full speed is of importance. A curve of torque plotted against speed (speed-torque curve) then is necessary.

**Rated Breakdown Torque** of an A.C. motor is the maximum torque which the motor will carry, with rated voltage and frequency applied to the motor, without an abrupt drop in speed. It indicates the peak load which the motor can carry without stalling or decelerating to a low speed.

**Pull-in Torque** of a synchronous motor is the maximum constant torque under which the motor will pull its connected inertia load into synchronism, at rated voltage and frequency, when its field excitation is applied. The speed to which a motor will bring its load depends on the power required to drive it; and whether or not the motor can pull the load into step from this speed, depends on the inertia of the revolving parts. Hence, pull-in torque cannot be determined unless the $WR^2$ of the external load and the torque of the load are known.

**Pull-out Torque** of a synchronous motor is the maximum sustained torque which the motor will develop continuously at synchronous speed with rated voltage, frequency, and normal excitation applied to the motor.

**STARTING CURRENT.**—It is characteristic of most motors that if full line voltage is impressed on their terminals at start (rotor at standstill) a current considerably in excess of the normal running current will be drawn from the line. This current usually is designated *locked rotor current*, and is defined as the current taken from the line with the rotor locked and with rated voltage (and frequency in the case of A.C. motors) applied. The term *free rotor current* sometimes is used; it is defined as 75% of the locked-rotor value.

In the case of D.C. motors, starting current must be held to certain limits (usually 150 to 300% of full load current), to prevent excessive burning of the motor commutator.

---

* Where 2-phase motors are supplied from a 3-wire circuit, the current in the common wire is 1.41 times the current in either other wire.

This prevents starting these motors on full voltage, except in sizes of 1/2 horsepower and below. In the larger sizes, the voltage must be reduced until the motor has accelerated. This usually is accomplished by means of a resistor temporarily inserted in series with the armature winding.

The full-voltage starting current of A.C. motors varies over a wide range for the different types of motors and may be as high as 10 times normal full-load current. Hence, in some cases reduced-voltage starting is necessary to prevent distortion of the windings and resultant failure of the insulation. However, with a few exceptions A.C. motors have the windings adequately braced, and full-voltage starting is permissible so far as the motor is concerned. But, in any case, reduced-voltage starting frequently is necessary to prevent undue voltage disturbance on the power lines. The starting current, flowing through transformers, transmission lines and feeders may cause a drop in voltage of sufficient magnitude to result in dimming of lights supplied from the circuit or cause other motors to stall or trip off the line.

Most power companies have established regulations governing the starting current which may be drawn by motors connected to their distribution systems. These regulations take a variety of forms, but two general types are common. The first type specifies the maximum starting current that may be drawn by any motor of a given horsepower rating, supplied with a given class of service. The rules of Table 4 are typical. The second type is based on the capacity to serve a given installation which, in general, is determined by the total electrical load being supplied. Usually the total current drawn by the motor in starting is not limited but if this total exceeds the value specified, it is necessary to employ a starter which will build the current up in steps, each step not exceeding the specified value, and with a short time interval (usually 1/2 second) between steps. Table 5 is typical of the second type of starting current regulation.

**Table 4.—Typical Motor Starting Current Regulations**

Based on Horsepower Rating of Motor

| Rating of Motor, Hp. | Maximum Allowable Locked Rotor Current, Amperes | | | | | | |
|---|---|---|---|---|---|---|---|
| | Direct Current | | 60-Cycle Alternating Current | | | | |
| | | | Single-phase | Three-phase | | | |
| | 230 Volts | 550 Volts | 220 Volts | 220 Volts | 440 Volts | 550 Volts | 2200 Volts |
| 1/2 and below * | 12 | 5 | 20 | 26.6 | ..... | ..... | .... |
| 3/4 and 1 | 12 | 5 | 27 | 26.6 | ..... | ..... | .... |
| 1 1/2 | 18 | 7.5 | 30 | 36.6 | ..... | ..... | .... |
| 2 | 24 | 10 | 40 | 46.6 | ..... | ..... | .... |
| 3 | 36 | 15 | 60 | 60 | 30 | 24 | .... |
| 5 | 45 | 20 | 100 | 86.6 | 43.3 | 34.6 | .... |
| 7 1/2 | 38 | 30 | 110 | 115 | 58 | 46 | 10 |
| 10 | 90 | 40 | 147 | 141 | 70.5 | 56 | 13.3 |
| 15 | 135 | 60 | ... | 197 | 98.5 | 78.6 | 20 |
| 20 | 180 | 80 | ... | 251 | 125 | 101 | 26.6 |
| 25 | 228 | 100 | ... | 304 | 152 | 122 | 33.4 |
| 30 | 270 | 120 | ... | 360 | 180 | 144 | 40 |
| 40 | 350 | 160 | ... | 380 | 190 | 152 | 40 |
| 50 | 450 | 200 | ... | 400 | 200 | 160 | 40 |
| 60 Hp. and above, amperes per Hp. | 9 | 4 | .... | 8 | 4 | 3.2 | 0.8 |

* If starting current does not exceed 30 amperes, these motors may be connected to 110-volt single-phase lines.

**Table 5.—Typical Motor Starting Current Regulations**

Based on Total Electrical Load *

| Type of Motor | Locked Rotor Starting Kva. Limitation Per Step |
|---|---|
| Single-phase, 110-volt | 2.2 kva. for motors up to and including 1/4 Hp.<br>3.5 kva. for motors over 1/4 Hp. |
| Single-phase, 220-volt | 2.5 kva. plus 0.25 kva. per installed kw. |
| 3-phase, 220- or 440-volt | 50 kva. plus 0.5 kva. per installed kw. |
| 3-phase, 2200-volt or above | 30 kva. plus 1.0 kva. per installed kw. |

* Notes:

1. The starting current limitations corresponding to the starting kva. limitations given above can be derived as follows: Current = (kva. × 1000)/($C$ × motor voltage); $C$ = a constant = 1 for single-phase motors, and 1.73 for 3-phase motors.
2. The installed kw. includes the motor under consideration. To convert Hp. to kw., multiply Hp. value by 0.746.
3. This specification does not limit the total kva. that may be taken by the motor in starting but may require that the total be built up gradually, or in steps which do not exceed the value determined from the table.

Where no power company regulation exists, the limits of motor starting current are determined by the voltage variation permissible, and the drop in voltage which results from a given increase in current. To avoid any perceptible light flicker it is necessary to prevent a sudden change in voltage in excess of approximately 2% of normal voltage; but in many cases a considerably greater voltage change, particularly if occurring at rare intervals, will not be objectionable. So far as motors are concerned, a 10 or 15% momentary drop in voltage usually is not serious, although in some special applications the resulting change in motor speed may cause difficulty. The drop in voltage caused by a given increase in current is determined by the rating and characteristics of the generating equipment, and by the resistance and reactance of transformers and feeders supplying the motor.

It is characteristic of most motors that if the starting current is reduced, for example, by means of a reduced voltage starter, the starting torque will also be reduced. Hence, the starting torque of the motor and the torque required by the load must be considered, as well as the starting current. A high ratio of starting torque to starting current (called *torque efficiency*) obviously is desirable, where severe starting current restrictions exist. This ratio varies over a wide range for the different types of motors and may vary with the type of control equipment employed.

**MECHANICAL FORMS.**—In its simplest form a motor may consist simply of the stator and rotor windings with their necessary magnetic structures. Certain types of small motors often are supplied in this form. The rotor then is mounted on a shaft of the driven machine which also is provided with a suitable support for the stator. However, a motor usually is furnished with shaft, two bearings, and mounting feet forming part of the stator frame. The bearings usually are carried by *end shields* which bolt to each end of the frame. On very large motors pedestal-type bearings often are used. In this case, a base may be provided which supports the stator and the bearing pedestals, or individual sole plates may be provided for each bearing pedestal and for each side of the stator frame.

Motors sometimes are supplied without mounting feet, being supported from the end shield on the drive end. This shield has a machined flange or face for bolting to the driven machine. This same construction may be used to wholly or partially support the driven machine by the motor. In this case the motor feet are retained.

Motors used with belt drives, usually are provided with a sliding base which permits adjustment of the motor position, in a direction perpendicular to the shaft, for tightening the belt. Up to certain sizes the standard, two-bearing motors are suitable for belt drive. In the larger sizes, an outboard bearing is provided.

All motors are available in the standard horizontal shaft construction. Most types also are available in the vertical shaft construction. In this case the motor is supported by feet or a ring base which forms part of, or is bolted to, the lower end shield. Two types of vertical motors are available. The *no-thrust type* is designed to carry no thrust load in addition to the weight of the rotor and the half coupling. The *thrust type* is designed to carry a specified amount of additional thrust load. Certain types of vertical motors can be obtained in *hollow-shaft construction.* These are used primarily for deep-well pumping, the hollow shaft allowing the pump shaft to be brought to the top of the motor for convenient coupling to the motor shaft, and for adjustment of its length.

The combination of a motor with an enclosed speed-reducing gear, built as an integral unit and designated *gear-motor* is offered by several manufacturers. The sizes available range from $^1/_8$ Hp. to approximately 75 Hp., with output shaft speeds of 13 to 600 r.p.m. An 1800 r.p.m. motor usually is employed. Various types of gear reduction units are used including the internal planetary with concentric output shaft, the worm and wheel type with right-angle shaft, and the straight helical gear reduction with parallel offset shaft. The gear-motor has a considerably lower cost than that of a conventional motor of corresponding output shaft speed.

Oil-lubricated sleeve-type bearings are standard for most types of horizontal motors. These may be waste-packed or oil-ring-lubricated. Ball and roller bearings are standard for certain types of motors, and are available for most types at slightly higher cost. These usually are grease-lubricated, although oil lubrication often is used on large high-speed motors, and for the thrust bearing of the larger vertical motors.

**ENCLOSING AND PROTECTIVE FEATURES.**—A motor normally requires the circulation of air through its interior for removing the heat resulting from the motor losses. If there is no restriction to the flow of ventilating air other than that necessitated by mechanical construction the motor is designated as *open type.* Although this type is most common and the lowest in cost, a number of other types are available, offering various degrees of enclosure.

**A Protected Motor** is one in which all ventilating openings in the frame are protected with a wire screen, expanded metal or perforated covers, the openings in which do not exceed 1/2 sq. in. area, and are of such shape as not to permit the passage of a rod larger than 1/2 in. diameter; if the distance of exposed live parts from the guard is more than 4 in., openings may be 3/4 in. diameter. This construction is designed to prevent accidental contact with rotating or live parts. Its use is confined largely to D.C. motors.

**A Semi-protected Motor** is one in which part of the ventilating openings in the frame, usually in the top half, are protected as in the case of a protected machine, the others being left open.

**A Drip-proof Motor** is one in which the ventilating openings are so constructed that drops of liquid, or solid particles, falling on the machine at any angle not greater than 15 deg. from the vertical, cannot enter the machine either directly, or by striking and running along a horizontal or inwardly inclined surface.

**A Splash-proof Motor** is one in which the ventilating openings are so constructed that drops of liquid or solid particles falling on the machine or coming towards it in a straight line at any angle not greater than 100 deg. from the vertical cannot enter the machine either directly, or by striking and running along a surface.

**A Totally-enclosed Motor** is one so enclosed as to prevent exchange of air between the inside and the outside of the case, but not sufficiently enclosed to be termed air-tight. It is used where necessary to protect the motor from dirt, moisture, chemical fumes or other harmful ingredients of the surrounding atmosphere.

**A Totally-enclosed, Fan-cooled Motor** is a totally-enclosed machine equipped for exterior cooling by means of a fan or fans, integral with the machine but external to the enclosing parts. It serves the same purpose as the totally-enclosed motor. The fan cooling feature is desirable on larger motors to dissipate the heat.

**An Enclosed, Self-ventilated Motor** is one having openings for the admission and discharge of ventilating air, which is circulated by means integral with the machine, the machine being otherwise totally enclosed. The openings are so arranged that inlet and outlet ducts or pipes may be connected to them. This construction serves the same purpose as the totally enclosed type where air free from harmful ingredients can be obtained within a reasonable distance. It also is used where it is necessary to prevent heat, resulting from the motor losses, from being discharged into the motor room.

**An Enclosed, Separately-ventilated Motor** is one having openings for the admission and discharge of the ventilating air, which is circulated by means external to and not a part of the machine, which otherwise is totally enclosed. These openings are so arranged that inlet and outlet ducts or pipes may be connected to them. This construction, rather than the enclosed self-ventilated construction, is employed on low-speed machines whose rotor fans do not develop sufficient pressure to circulate the ventilating air through the required duct length.

Both the enclosed self-ventilated and the enclosed separately ventilated type machines may be provided with a closed system of ventilation; that is, the hot air discharged from the machine may be cooled and then recirculated through the machine. Cooling usually is accomplished by water circulated through surface air coolers. The closed system of ventilation generally is restricted to rather large machines.

**An Explosion-proof Motor** is one in an enclosing case, which is designed and constructed to withstand an explosion of a specified gas or dust which may occur within it, and to prevent the ignition of the specified gas or dust surrounding the motor by sparks, flashes or explosions which may occur within the machine casing. The National Electrical Code (Article 32) classifies locations in which hazardous gas or dust may be present, in accordance with the degree of hazard involved as follows:

Class I: Group *A*, Atmospheres containing acetylene; Group *B*, Atmospheres containing hydrogen; Group *C*, Atmospheres containing ethyl ether vapor; Group *D*, Atmospheres containing gasoline, petroleum, naphtha, alcohols, acetone, lacquer solvent vapors, and natural gas.

Class II: Group *E*, Atmospheres containing metal dust; Group *F*, Atmospheres containing carbon black, coal, or coke dust; Group *G*, Atmospheres containing grain dust.

Since it is impractical to design a motor which is gas tight, motors for Class I locations are so constructed as to permit explosions within the motor without ignition of the surrounding atmosphere. This is accomplished by: 1. Making the enclosing parts sufficiently strong to withstand safely the maximum pressure caused by ignition of the most flammable mixture of the gas involved; 2. Providing long fits with close clearances at all joints, and at the shaft opening, to cool the flame to a point where ignition of the outside atmosphere is prevented. Practically no motors are available for the more hazardous locations of Groups *A*, *B* and *C*. On the other hand, rather complete lines of motors suitable for Class I, Group *D* conditions are available. It is impractical to build motors of this type in the very large sizes, the present (1937) upper limit being about 200 Hp.

Motors for Class II locations are built totally-enclosed (or totally-enclosed fan-cooled), with all joints, etc. sufficiently tight to exclude the specific dust. Fairly complete lines of motors are available for Class II Group *G* locations.

The Underwriters' Laboratories, Inc. established and maintained by the National Board of Fire Underwriters offer a testing and inspection service available to manufacturers of equipment for hazardous locations. Motors which have been tested and inspected by them are provided with a label so indicating. Since most inspection authorities look to the Underwriters' Laboratories for guidance as to the suitability of equipment for hazardous locations, motors provided with this label generally are acceptable for use in the specified atmospheres anywhere in the United States. In general, motors with the Underwriters' label are available only for Class I, Group *D* and Class II, Group *G* locations.

Motors for installation in mines come under the jurisdiction of the U. S. Bureau of Mines. This body does not issue approvals covering a motor or controls, but approves only a complete power-using assembly consisting of a machine, such as pump, coal cutter, conveyor, etc., combined with the motor which drives it and the complete control equipment and wiring. However, certain types of motors are available, which have passed the inspection and tests of the Bureau of Mines, indicating that they are eligible for ultimate approval, without further tests, as part of a complete power-using assembly.

## 2. SMALL POWER MOTORS

Small power or fractional Hp. motors are motors built on frames having a continuous rating of less than 1 Hp., open type, at 1700–1800 r.p.m. Standard horsepower and speed ratings of small power motors are given in Table 6. The various types in general use are as follows: *a.* Single-phase motors: 1. Shaded-pole; 2. Split-phase; 3. Repulsion-start induction (and repulsion-induction); 4. Capacitor start; 5. Capacitor; 6. Series-wound; 7. Synchronous (non-excited).

*b.* Polyphase motors: 1. Squirrel-cage induction; 2. Synchronous (non-excited).

*c.* Direct-current motors: 1. Shunt-wound; 2. Series-wound; 3. Compound-wound.

*d.* Universal motors (operate from either A.C. or D.C.): 1. Series-wound; 2. Compensated-series-wound.

**SINGLE-PHASE MOTORS** are available in a variety of types, but practically all operate essentially as squirrel-cage induction motors. Since a normal single-phase

Smaller sizes usually are rated in watts output (746 watts = 1 Hp.).

induction motor does not develop any starting torque, it must be provided with an auxiliary starting winding or phase-shifting device. The essential difference between the various types of single-phase motors lies in the type of starting winding or phase-shifting device employed.

**Shaded-pole Single-phase Motors** have a squirrel-cage rotor winding and a concentrically-wound single-phase stator winding. A portion of each stator pole is "shaded" by a single turn of heavy copper wire. Current, which is out of phase with the current in the main winding, is induced in the shading coil. This results in a revolving magnetic field similar to that of a polyphase induction motor, and hence starting torque is developed. Motors of this type are inefficient, and have rather low starting torque. However, in the small sizes they are the most economical design. They are used in ratings up to 10 or 15 watts ($^1/_{75}$ to $^1/_{50}$ Hp.) for such applications as small fans, timing devices, instruments, relays, toys, sign flashers, small motion picture projectors, and miscellaneous control devices. They are designed for a particular direction of rotation which cannot be changed after the motor is built.

**Split-phase Motors** have squirrel-cage rotors and two-phase stators, with one of the phases wound for relatively high resistance. Since the ratios of resistance to reactance of the two phases are not equal, the currents in the phases are not of the same time phase, and approach the relations of a true two-phase motor. Hence, a revolving magnetic field is produced and starting torque is developed. As the losses in the high resistance winding are high, it must be disconnected when the motor gets up to speed. The disconnecting switch usually is operated by a centrifugal mechanism on the rotor. These motors are used in ratings from $^1/_{60}$ to $^1/_3$ Hp. on a variety of applications whose power requirements fall within this range; typical are advertising devices, fans, blowers, oil burners, kitchen appliances, machine tools, mechanical office equipment, pumps, textile and laboratory equipment, washing and ironing machines.

**Repulsion-start Induction and Repulsion-induction Motors** have a single-phase distributed winding on the stator, and a commutated winding, similar to that of a D.C. machine, on the rotor. The brushes bearing on the commutator are spaced 180 electrical degrees apart and are short circuited. Repulsion-start induction motors also have a centrifugal device which short-circuits all of the commutator segments when the motor has accelerated to a certain speed, converting the rotor winding to a squirrel-cage winding. Thus the motor starts as a repulsion motor, but runs as an induction motor. The centrifugal device sometimes is arranged to lift the brushes of the motor as well as to short circuit the commutator segments. Repulsion-induction motors, on the other hand, do not have any centrifugal device, but instead have a squirrel-cage winding on the rotor in addition to the commutated winding. The squirrel-cage winding is placed below the commutated winding and is arranged to have a high reactance. At low motor speeds (high slip frequency) very little current flows in the squirrel-cage winding, and the motor starts essentially as a repulsion motor. When the motor reaches full-speed, the frequency of the induced currents is low, so that considerable current flows in the squirrel-cage winding and the motor operates essentially as an induction motor. Repulsion-start induction or repulsion-induction motors generally are offered by manufacturers in ratings of $^1/_6$ Hp. and larger. High starting torque, low starting current, and relatively low cost are important features. Typical applications are pumps, compressors, machine tools, hoists, conveyors, garage and service station equipment, and woodworking machinery.

**The Capacitor-start Motor** is provided with a squirrel-cage rotor, and with a main winding and an auxiliary winding on the stator. A capacitor (usually mounted on top of the motor) is connected in series with the auxiliary winding to provide the necessary shift in time phase of the current flowing through it. Since the capacitor is intermittently rated it must be disconnected for normal operation. This usually is accomplished by a switch operated by a centrifugal mechanism on the rotor. Capacitor-start motors generally are available in ratings of from $^1/_8$ to $^1/_4$ Hp., and are used for such applications as oil burners, stokers, pumps, and household appliances.

**The Capacitor Motor** is provided with a continuously rated capacitor, and, therefore, the auxiliary winding with the capacitor in series may be left in the circuit during running as well as starting. The capacitor is selected to give best operation at full speed, *i.e.*, maximum efficiency and minimum noise and vibration. If the same capacitance is used during the starting and running periods the motor develops only 40 to 60% starting torque and is known as the *low-torque* capacitor motor. The *high-torque* capacitor motor, which develops 275 to 350% starting torque, is obtained by increasing the capacitance in series with the auxiliary winding during the starting period. This usually is accomplished either by: 1. Providing an additional intermittently-rated capacitor which is connected in parallel with the main capacitor during the starting period; 2. Energizing the capacitor through an auto-transformer, provided with two taps, which allows the use of a higher voltage ratio during the starting period. The change from starting to running connections on the capacitor is accomplished by a switch operated by a centrifugal mechanism on the rotor, or a relay is used, operated by the rise in voltage across the auxiliary winding as the motor comes up to speed. High power-factor and efficiency, and quiet operation are important features of capacitor motors. They generally are available in ratings of $^1/_8$ Hp. and larger. The low-torque capacitor motor can be used only on such applications as direct-connected fans which require little starting torque. The high-torque capacitor motor is a general purpose machine of increasing popularity. Typical applications include reciprocating compressors, pumps, fans, and blowers. The capacitor motor frequently is used for variable speed operation of fans, the speed change being accomplished by varying the voltage impressed on the motor terminals.

**The Series-wound Single-phase Motor** is similar in construction and principle of operation to the series-wound direct-current motor. It employs a stationary field winding and a commutated rotor (armature winding), the two being connected in series. Like the series D.C. motor, it is of the varying speed type, that is, its speed increases as the load decreases. Usual full-load speeds range from 1500 to 5000 r.p.m.; no-load speeds range from 150 to 200% of full-load speeds. The principal advantages of series motors are their extreme compactness and light weight for the power delivered. Hence, they are particularly suitable for application to portable devices, such as vacuum cleaners and portable tools of all types. Since they usually are " built-in " the power-using device, they frequently are supplied as " motor parts," that is, the bare stator and rotor, without bearings or feet, the bearings and stator support being incorporated in the driven machine.

**Synchronous Motors** in the small power sizes usually are built as *reluctance motors.* The stators are similar to those of single-phase induction motors, and may be of the shaded-pole, split-phase, or capacitor type. The rotor has a squirrel-cage winding, and the core is shaped to provide projections (salient poles) corresponding to the number of poles for which the stator is wound. The motor starts as an induction motor, but upon reaching a speed near synchronism, it " pulls into step," due to the effect of the salient poles, and operates at exactly synchronous speed. Unlike the large-power synchronous motor, which has a field winding on the rotor supplied with D.C. excitation, and which operates at unity or leading power-factor with high efficiency, the reluctance motor operates at a lagging power-factor and has a rather low efficiency. Hence, it is used only where exact synchronous speed is required. Typical applications include electric-clocks, time switches, relays, and recording meters.

Another type of synchronous motor available in the small-power sizes is the *hysteresis motor.* Its construction is similar to that of the reluctance motor except that the rotor is perfectly cylindrical and does not have a squirrel-cage winding. Its operation depends on the permanent magnetism induced in the rotor by the magnetic field of the stator. It develops a constant torque from zero to synchronous speed. It is used principally for phonograph turntable drive.

**POLYPHASE MOTORS.—Squirrel-cage Induction Type Motors** meet the requirements of practically all applications in the small power field. They develop a high starting torque with a starting current well within the limits of polyphase systems. Their efficiencies are slightly higher than those of single-phase motors. Polyphase motors are generally available in sizes of $^1/_6$ Hp. and larger at 110, 220, 440, and 550 volts.

**Synchronous** motors of the reluctance type are employed where exact synchronous speed is required. They are similar to the single-phase motors of this type except that no starting winding or phase-splitting device is necessary.

**High-frequency Polyphase Motors** often are used on portable tools, textile machinery, and other high speed motor applications where the number required justifies the installation of special generating or conversion equipment to supply the high-frequency power. A frequency of 180 cycles usually is employed, giving a synchronous speed (2-pole motors) of 10,800 r.p.m. The advantages are a saving in cost, size, and weight over 60-cycle induction motors. As compared to the series motor, the high-frequency polyphase motor requires less maintenance, since it has no brushes or commutator and has a higher efficiency and better speed regulation.

**DIRECT-CURRENT MOTORS** of the **shunt-wound** or **compound-wound** type are used for most applications. In the smaller sizes (approximately $^1/_{20}$ Hp. and below) shunt-wound motors are standard, while in the larger sizes, the standard is compound-wound. The **series-wound** motor is used where its varying speed characteristics and high no-load speed is not objectionable. It develops a very high starting torque, but has a limited output at the higher speeds.

**UNIVERSAL MOTORS,** which operate from either single-phase A.C. or D.C. power, are all of the series-wound type; that is, they have a field winding on the stator which is connected in series with a commutated winding on the rotor. The **straight series-wound**

motor has a salient pole field winding on the stator, like the ordinary D.C. motor, while the **compensated-series-wound** motor has a distributed winding arranged in slots around the periphery of the stator. The latter has the advantages of better speed regulation and commutation, and higher starting torque, while the former is simpler in construction and more easily ventilated. In general, the straight series-wound motor is used in sizes up to approximately 1/3 Hp., while the compensated-series-wound motor is used in the larger sizes. It is not feasible to build universal motors for low speed operation, the minimum full load speed ranging from 1800 r.p.m. on the larger sizes to 5000 r.p.m. on the smaller sizes. Typical full-load speed ratings are 5000, 7500 and 10,000 r.p.m., with no-load speeds ranging from 12,000 to 18,000 r.p.m. Universal motors are used on a variety of applications including portable tools, office appliances, vacuum cleaners, motion picture projectors, kitchen appliances, sewing machines and portable equipment in general.

## Operating Characteristics

**TEMPERATURE RISE.**—The standard temperature rise of small power motors, when operating under normal conditions, is 40° C., measured by thermometer, for open and drip-proof motors, and 55° C. for totally-enclosed motors. The motors frequently are offered in two general types designated " For short annual service " and " For long annual service." Both types can be operated continuously, but the latter type is recommended for applications where the motor must operate more than 1000 hours annually. They are designed especially for good running characteristics, such as high efficiency and power-factor. In the short annual service type, these characteristics may be sacrificed to some extent to obtain higher torques and lower costs.

**EFFICIENCY.**—Minimum efficiencies, power-factors, and apparent efficiencies of single-phase, 60-cycle, induction motors as established by N.E.M.A. are given in Table 7. The standard motors offered by the manufacturers have characteristics equaling or exceeding these values. In general, the efficiencies of polyphase induction motors are somewhat higher than those of single-phase motors of corresponding ratings, while the efficiencies of direct-current motors are slightly lower than those of single-phase motors.

**STARTING CURRENT.**—The maximum locked-rotor starting currents of single-phase motors as established by N.E.M.A. are given in Table 8. The locked-rotor currents

of polyphase squirrel-cage induction motors vary between 400 and 800% of full-load current.

**TORQUE.**—Minimum torque values for 60-cycle induction motors as established by N.E.M.A. are given in Table 9. Typical speed-torque curves are shown in Figs. 1 and 2. D.C. motors, shunt- or compound-wound, develop 500% or more starting torque on full voltage.

**VOLTAGE VARIATION.**—Small power motors should operate successfully at rated load (and rated frequency for A.C. motors) at any voltage not more than 10% above or below normal, but not necessarily in accordance with the standards of performance established for operation at normal rating. An exception to this rule applies to the series-type universal motors for which the maximum allowable voltage variation is 6%. The starting currents of all types are proportional to the applied voltage and the starting,

pull-up, and breakdown torques are approximately porportional to the square of the voltage.

### Mechanical Features

Small power motors may be obtained as bare rotors and stators (with or without feet) for mounting directly on the driven machine. However, the usual construction consists of a stator frame provided with mounting feet and end-shield type bearings. Motors with the drive end-shield machined for bolting to the driven machine are available. Vertical motors, as well as the standard horizontal motors, are available in all types.

Wool-yarn-packed sleeve bearings are standard, but ball bearings can be obtained at extra cost. Vertical motors usually are provided with ball bearings, as are horizontal motors which are required to take considerable axial thrust.

Single-phase induction motors inherently produce a pulsating torque, resulting in vibration of the motor frame which, if transmitted to the motor support, may result in objectionable noise. Hence, such motors frequently are furnished with a resilient rather than a rigid connection between the motor frame and the motor base. This resilient connection may consist of rubber cushions, or of metal springs of sufficient flexibility to prevent or greatly reduce the transmission of vibration to the supporting structure. Some manufacturers offer motors with a resilient mounting combined with an automatic belt tightener base, which maintains a belt tension just sufficient to prevent slippage at all loads throughout the operating range.

Gear-motors of the various electrical types are available in ratings from 1/8 to 3/4 Hp. with output shaft speeds of 11 to 575 r.p.m. Both concentric and right-angle shaft types are available. The latter employ worm-and-wheel reduction units and have lower costs, but considerably lower efficiency. The horsepower output rating of a gear-motor may be considerably less than the rating of the motor itself, the difference depending on the type of gear and the speed ratio.

Standard motors are of the open or drip-proof construction, but practically all types can be obtained in the totally-enclosed construction. Most types also are available in the explosion-proof construction for Class I, Group *D* locations. See p. 25–17.

**WEIGHTS AND DIMENSIONS.**—Approximate net weights and overall dimensions of open, horizontal motors for long annual service are given in Fig. 4 and Table 10. The dimensions of totally-enclosed, and enclosed motors, excepting the explosion-proof type, are essentially the same as those of open motors. Explosion-proof motors usually have slightly greater overall dimensions. Motors for short annual service are, in general, slightly smaller than the motors for long annual service. The overall dimensions of vertical motors do not differ greatly from those of horizontal machines when shifted 90 deg.

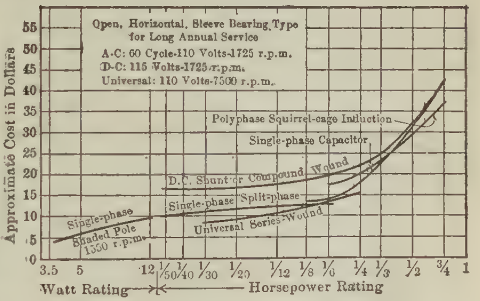

Fig. 3. Approximate 1936 Cost of Small Power Motors

**COSTS.**—Approximate costs (1936) of open, horizontal, sleeve bearing motors are given in Fig. 3. The figures shown are for 110-volt A.C., and 115-volt D.C. motors having a full-load speed of 1725 r.p.m. (excepting the universal motors). Shaded-pole, split-phase, and universal motors for 220 volts are slightly higher in cost, as are 230 volt D.C. motors. Polyphase motors are offered for 440 and 550 volts, as well as 110 and 220 volts, but the former are slightly higher in cost.

In general, 3450 r.p.m. motors are more costly than 1725 r.p.m. machines, although in the larger sizes the reverse is true. All 1140 r.p.m. machines are more costly than those rated 1725 r.p.m. Universal motors rated 5000 r.p.m. are more costly, and those rated 10,000 r.p.m. are less costly, than 7500 r.p.m. machines. Ball bearings, enclosed construction, vertical mounting, and special mechanical features result in increased cost.

## 3. SINGLE-PHASE LARGE POWER MOTORS

Standard horsepower and speed ratings of large power, single-phase motors are given in Table 11. The following types are available: *a*. Repulsion-start induction (and repulsion-induction); *b*. Capacitor; *c*. Brush-shifting repulsion; *d*. Polyphase induction with phase-shifting starter.

For details of construction and principle of operation of types *a* and *b*, see p. 25–19.

**Repulsion-start Induction and Repulsion-induction Motors** are available in sizes up to 10 Hp. Their high starting torque, low starting current, and low cost make them the most popular of all types. They are used on practically all applications requiring single-phase motors.

**Capacitor Motors** are more costly than the repulsion-start induction or repulsion-induction type, but their simple construction, high efficiency and power-factor, and inherently quiet operation are features which frequently justify their use. In addition to their general-purpose capacitor motors, which are of the high torque type and are used on such applications as pumps, compressors, conveyors and machine tools, manufacturers offer special low-torque and high-torque capacitor motors for fan drives. The former are for use on direct-connected fans only, while the latter are suitable for belt-driven fans. Both types are specially designed for quiet operation, and with a somewhat lower full-load speed (higher slip) than the general purpose motors. The latter feature allows adjustable speed operation down to approximately 50% speed, by means of suitable control which varies the voltage impressed on the motor. Multi-speed capacitor motors also can be obtained.

**The Brush-shifting Repulsion Motor** is similar in construction to the repulsion-induction motor except that no squirrel-cage winding is provided on the rotor. Instead, a compensating transformer, connected in series with the stator winding, supplies power to brushes located at 90 deg. from the main brushes. By varying the position of the main brushes, the speed of the motor can be varied through a range of 2.5 to 1 on a constant torque load. The motor has varying speed characteristics, the no-load speed being approximately 60% above synchronous speed. Fig. 5 shows typical speed-torque curves for various brush settings. Ratings available range from $^1/_4$ to 3 Hp. at 1800/720 r.p.m. Typical applications include job printing presses, automobile generator test benches, balancing, polishing, and winding machines.

Single-phase motors are seldom used in sizes above 10 Hp. Hence, none of the types described above is available in the higher ratings. Where a larger single-phase motor is required, it is usual to use a polyphase induction motor with a split-phase starter of the resistance-reactance type. The horsepower output of a polyphase induction motor operating single-phase is approximately $^1/_2$ of its normal rating.

## Operating Characteristics

**TEMPERATURE RISE.**—The standard temperature rise of large power, single-phase motors when operating under normal rated conditions is 40° C., measured by thermometer, for the general-purpose open type; for splash-proof motors, it is 50° C.; for totally-enclosed motors, it is 55° C. Standard open motors having a temperature rise of 40° C. usually are given a *service factor* of 1.15; that is, the manufacturers guarantee successful operation at 1.15 times rated load without injurious heating, although the efficiency and power-factor may be slightly different from the rated load values.

**EFFICIENCY.**—Typical full-load efficiencies and power-factors of repulsion-induction type motors are given in Fig. 6. Capacitor motors will, in general, have slightly higher

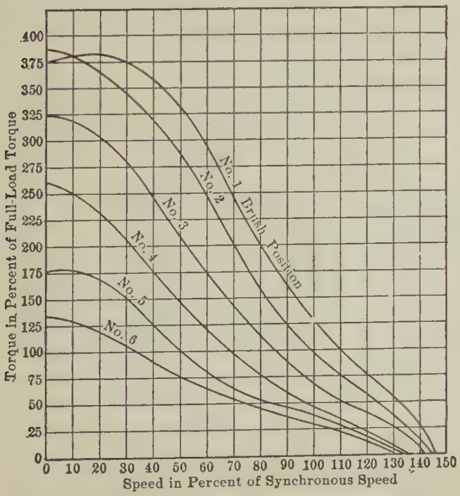

FIG. 5. Speed-torque Curves of Typical Brush Shifting Repulsion Motors

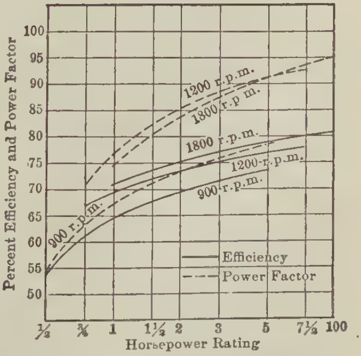

FIG. 6. Approximate Full-load Efficiency and Power Factor of 110- and 220-Volt, 60 Cycle, Repulsion Induction Motors

efficiencies and about the same power-factors, while repulsion-start induction motors have the same efficiencies but lower power-factors.

**TORQUE.**—Typical starting and breakdown torque values for constant-speed single-phase motors are given in Table 12. **Starting currents** range between 300 and 450% of full-load current. Brush-shifting repulsion motors have starting torques of 250 to 300% with the brushes in the high-speed position, reducing to 125% as the brushes are shifted to the low speed position. Their breakdown torques are approximately 300% of full-load torque.

**VOLTAGE VARIATION.**—Large power, single-phase motors should operate successfully at rated load and frequency at any voltage not more than 10% above or below normal but not necessarily in accordance with the standards of performance established for operation at normal rating. The starting currents are proportional to the applied voltage, and the starting, pull-up, and breakdown torques are proportional to the square of the voltage.

## Mechanical Features

Large power, single-phase motors usually are furnished with feet on the stator frame, and with end-shield type bearings. They are also available with the drive end shield machined for bolting to the driven machine. Vertical motors, as well as standard horizontal motors, can be obtained. The former may be obtained with ring, four-leg, or tripod base.

Sleeve bearings, wool-yarn-packed or oil-ring-lubricated, are standard for most horizontal machines. Ball bearings are standard on vertical and totally-enclosed motors, and can be obtained on other machines at extra cost. All motors can be obtained with pulleys and sliding bases for two-bearing belt drive. Gear motors are available in ratings from 1 to 5 Hp. with output shaft speeds of 13 to 600 r.p.m.

Standard motors are of the open type, but splash-proof, totally-enclosed, fan-cooled, and explosion-proof (Class I, Group *D* conditions) motors also are available.

**WEIGHTS AND DIMENSIONS.**—The N.E.M.A. has standardized mounting dimensions for various types of motors, indicating these dimensions by a series of frame numbers. These are used by all manufacturers for motors which have the standardized dimensions. The frame numbers and weights assigned to the various ratings of open and totally-enclosed, fan-cooled, 60- and 50-cycle, 110- and 220-volt single-phase motors are given in Table 13. The mounting dimensions corresponding to these frame numbers are given in Table 14 and Fig. 7 for horizontal machines, and Table 15 and Fig. 8 for vertical machines.

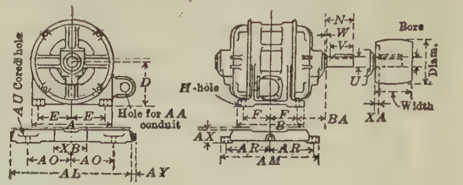

Fig. 7.

* The standard pulley for 3000 and 3600 r.p.m. motors in frames 324 and 326 is 5 in. diameter, 6 3/4 in. width overall, and the *XA* dimension is 1/4 in.

Note 1.—Dimension *D* will never be exceeded. When exact dimension is required, shims up to 1/32 in. may be necessary on frame sizes whose dimension *D* is 8 in. and less, and on larger frames, shims up to 1/16 in. may be necessary.

Note 2.—Tolerances on shaft extension diameters are: Shaft diam., 3/4 in. to 1 1/2 in. inclusive, + 0.0000 in., − 0.0005 in.; shaft diameter 1 5/8 in. to 3 3/8 in. inclusive, + 0.000 in., − 0.001 in.

† Dimension *XB* represents total movement of motor on base for tightening belt.

Note 3.—Tolerances on keyways: Width 3/16 in. to 3/4 in. inclusive, + 0.000 in., − 0.002 in.

Note 4.—Tolerances in making keyways parallel to center line of shaft: Shaft diam. 3/4 in. to 1 1/2 in. inclusive, 0.002 in.; shaft diameters 1 5/8 in. to 3 3/8 in. inclusive, 0.003 in. Limited to 12 in. in length.

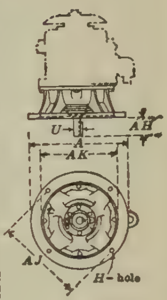

Fig. 8

Note 1.—Available length of shaft extension for coupling hub must be at least two times the diameter.

* Dimensions given also apply to hollow shaft motors, with the exception of *AH*, *U*, key dimensions, and Note 1.

† The tolerance for the *AK* dimension shall be: +0.005 in., −0.000 in.

**COSTS.**—Approximate costs of open, horizontal, 60- and 50-cycle, 110- and 220-volt, sleeve-bearing motors of the repulsion-induction or repulsion-start induction type are given in Fig. 9. Capacitor motors have a somewhat higher cost (increase ranges from 5 to 75%). Brush shifting repulsion motors (1800/720 r.p.m.) have a cost approximately twice that of corresponding ratings of 1800 r.p.m. repulsion-induction motors. Special mechanical features increase the cost.

## 4. POLYPHASE INDUCTION LARGE POWER MOTORS

Standard horsepower and speed ratings of large power, polyphase induction motors are given in Table 16. Motors rated 200 Hp. or less, having a continuous time rating, and for use without restriction to a particular application are designated general-purpose motors.

**TYPES** of polyphase induction motors in general use are as follows:

*a.* Squirrel-cage motors: 1. Class A, normal torque, normal starting current; 2. Class B, normal torque, low starting current; 3. Class C, high torque, low starting current; 4. Class D, high slip. *b.* Wound-rotor motors. *c.* Multi-speed motors. *d.* Quiet operating motors. *e.* Crane and hoist motors. *f.* Elevator motors. *g.* Adjustable-speed brush-shifting motors. *h.* Adjustable varying-speed brush-shifting motors.

**Squirrel-cage Motors.**—The various types of squirrel-cage motors differ principally in their starting characteristics. Class A motors develop normal starting torque (Table 17) and draw a starting current of 6 or 7 times full-load current. They have the highest efficiencies and power-factors, and the lowest cost of all types, and meet the requirements of the majority of applications. Although these motors are suitable for starting on full voltage, reduced voltage starting sometimes is required for motors rated 7 1/2 Hp. and larger to meet local starting current regulations.

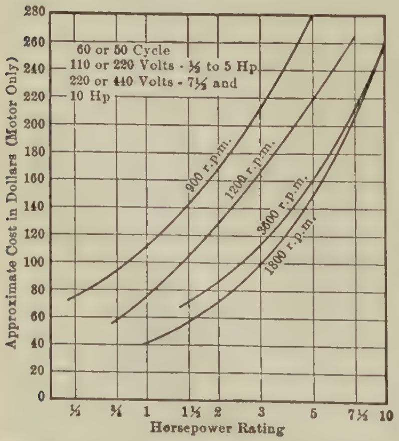

Fig. 9. Approximate 1936 Cost of Open Sleeve-bearing Repulsion Induction or Repulsion-start Induction Motors

NOTE 1.—The 1500 r.p.m., 25-cycle ratings apply to squirrel-cage motors only.

NOTE 2.—The ratings above the heavy lines are suitable for belt drive, while those below are for direct connection only.

NOTE 3.—Standard 50-cycle horsepower ratings are the same as for 60 cycles, but the speeds are 5/6 those of the 60-cycle speeds.

**Table 17.—Torques and Starting Currents of 60-cycle, Class A, Squirrel-cage Induction Motors**

| Rev. per min. | 3600 | 1800 | 1200 | 900 | 720 | 600 | 514 | 450 |
|---|---|---|---|---|---|---|---|---|
| | Percent of Full-load Values | | | | | | | |
| Min. starting torque | 150 | 150 | 135 | 125 | 120 | 115 | 110 | 105 |
| Min. breakdown torque | 200 | 200 | 200 | 200 | 200 | 200 | 200 | 200 |
| Typical starting current | 780 | 710 | 660 | 570 | 520 | 500 | 500 | 500 |

Class B motors are built with a high-reactance rotor winding, which limits the starting current to about 5 times full-load current. This allows the use of full voltage starting in some cases where reduced voltage starting would be necessary if a Class A motor were used. The starting torques are the same as for the Class A motors, but the power-factors and breakdown torques are slightly lower.

Class C motors, usually built with a "double squirrel-cage" rotor winding, combine high starting torque (200% or more) with the low starting current of Class B motors. Their power-factor, efficiency, and breakdown torques are all somewhat lower than for

Class A motors. They are used on such applications, as reciprocating compressors which start under load, where high starting torque and good running characteristics are required.

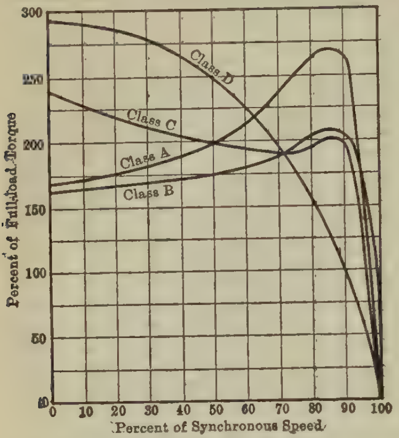

Fig. 10. Typical Speed-torque Curves of Squirrel-cage Induction Motors

Class D motors, built with a high-resistance rotor winding, develop a high starting torque with low starting current, but have high slip at running speed and low efficiency. They are used principally for drives imposing rapidly recurring peak loads, and for drives involving a heavy starting duty, but light or intermittent running duty. In the former case, a fly-wheel frequently is provided to equalize the load peaks. This type of motor should not be used to drive a continuous steady load, as its efficiency is quite low.

Fig. 10 shows typical speed-torque curves, and Fig. 11 shows typical speed-current curves of each of the four types of squirrel-cage induction motors.

**The Wound-rotor Induction Motor** has an insulated 3-phase winding on the rotor, whose terminals are connected to three slip rings. Stationary brushes bear on the latter, through which the rotor circuit is completed external to the motor. By inserting various amounts of resistance in series with the rotor winding the torque and current characteristics of the motor can be varied as shown in Fig. 12. High starting torque thus can be obtained with very low starting current. With all resistance cut out, the characteristics of this motor are similar to those of the Class A squirrel-cage motors, but with somewhat lower efficiency. With suitable control, wound-rotor motors can operate continuously at reduced speeds down to 50% speed, but the efficiency is reduced in proportion to the speed. At reduced speeds the motor has varying speed characteristics, *i.e.*, a change in load results in considerable change in speed. Wound-rotor motors are used occasionally where the application requires a high ratio of starting torque to starting current (high torque efficiency), or where severe accelerating duty is involved. However, these motors are used principally on applications requiring an adjustable speed drive. They can be used economically for driving variable torque loads (centrifugal pumps, fans, etc.) at reduced speeds, but are not economical for continuous reduced speed operation of constant torque loads.

**Multi-speed Squirrel-cage Motors** may be provided with: 1. A single stator winding which is connected to give either one of two speeds; 2. Two or more stator windings giving a corresponding number of speeds; 3. A combination of [1] and [2]. The single-winding motor is lowest in cost, and has the best characteristics, but it gives only two speeds having a ratio of 2 : 1. Two or more windings must be employed where more than two speeds, or other speed ratios, are required.

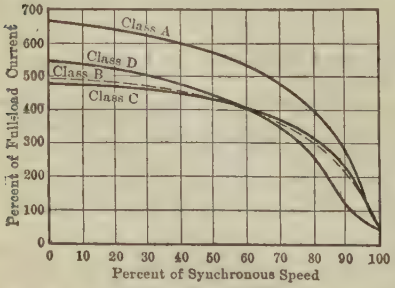

Fig. 11. Typical Speed-current Curves of Squirrel-cage Induction Motors

Multi-speed motors may be classified into three general types: *a. Variable torque motors* have horsepower ratings at each speed proportional to the square of the speed (*viz.*, 20/5 Hp., 1800/900 r.p.m.), and are used for driving centrifugal pumps, fans, and agitators; *b. Constant torque motors* have horsepower ratings at each speed directly proportional to the speed (*viz.*, 30/20/15/10 Hp., 1800/1200/900/600 r.p.m.), and are used for such applications as conveyors, stokers, reciprocating compressors, printing presses, and dough mixers; *c. Constant horsepower motors* have the same horsepower rating at all speeds (*viz.*, 5 Hp., 1800/600 r.p.m.). Typical applications are lathes, boring mills, planers, radial drills, grinders, milling machines, winches, and drag line scrapers. Multi-speed squirrel-cage motors may have electrical characteristics corresponding to Classes A, B, C, or D, but in general the same characteristics are obtained at all speeds.

**Multi-speed Wound-rotor Motors** also are available. Where speed adjustment (by varying the secondary resistance) is required on all speeds, only two speeds can be obtained and these must have a ratio of 2 : 1. In many applications, speed adjustment is required on only one speed, in which case two-, three-, or four-speed motors, having any synchronous speeds required, can be obtained. Except on the speed which is to be adjusted, the rotor winding operates short-circuited as a squirrel-cage motor. Typical applications of multi-speed wound-rotor motors include hoists for dragging and lifting service, conveyors, elevators, oil well pumps, and rotary car dumpers.

**Quiet-operating Motors** may be of the squirrel-cage (Class A, B, C, or D) or the wound-rotor type. There is no apparent difference in the construction of these motors and the standard motors, but the details of design, such as slot combination, uniformity of air gap, and magnetic flux density are given special consideration. Though more costly than standard motors, quiet-operating motors often are used in such locations as office buildings, schools, and hospitals, where noise must be kept to a minimum. The most common application of the quiet-operating motor is the driving of ventilating fans.

* The frame numbers given for 3600 r.p.m. motor of 2 to 7 1/2 Hp. inclusive, and lower speed motors in frames 365 and smaller, also apply to totally-enclosed, fan-cooled motors.

† Standard mounting dimensions for these frame numbers are given in Figs. 7 and 8, and Tables 14 and 15.

‡ These frame numbers will apply also for 2200-volt motors.

**Crane and Hoist Motors** are available in both the squirrel-cage and wound-rotor types. The squirrel-cage motors are similar to Class D motors, having a high starting torque, low starting current and high full-load slip. The open motors are rated 30 min., 50° C. temperature rise, and the totally-enclosed motors are rated 15 min., 55° C. temperature rise. They are used mainly on the smaller hoists. The open type wound-rotor motors are rated 30 min., 50° C. temperature rise in sizes up to 40 Hp., and are rated 1 hour, 50° C. temperature rise in the larger sizes. The totally-enclosed, wound-rotor motors are rated 30 min., 55° C. temperature rise in all sizes. All crane and hoist motors can be obtained with a shaft extension on both ends, one for the driving pinion or coupling, the other for a brake. In addition to crane and hoist duty, these motors often are used for such applications as bascule lift and swing bridges, rotary car dumpers, larry cars, coke pushers, and hydraulic gates.

**Single-speed Elevator Motors** may be of the squirrel-cage or wound-rotor type. The former are similar to the Class D motors, having high starting torque and low starting current. They are available in ratings from 1 to 60 Hp. at speeds of 720 to 1800 r.p.m., and are intermittently rated, 30 min., 50° C. temperature rise. They are used on low-speed freight and passenger elevators, operating at a maximum car speed of about 150 ft. per minute. The squirrel-cage motor is most popular, and is used also on other applications, such as skip hoists. The wound-rotor type is used occasionally, since it is suitable for a greater number of starts and stops per hour.

**Two-speed Elevator Motors** also are available. They are either squirrel-cage or combination squirrel-cage and wound-rotor machines. The former may employ a single winding, giving a 2 : 1 speed ratio, or separate windings in the same slots giving a speed ratio up to 6 : 1. A high-resistance rotor winding, giving Class D characteristics, is employed. These motors are available in ratings from 10 to 60 Hp., with a top speed of 1200 or 900 r.p.m., and are rated 1 hour, 50° C. temperature rise on the high speed. The combination squirrel-cage and wound rotor motor really consists of two motors, a high-speed (900 r.p.m.) wound-rotor motor and a low-speed (225 or 150 r.p.m.) squirrel-cage motor, built as a single unit. These motors are available in ratings of 20 to 75 Hp., and are rated 2 hours, 50° C. temperature rise on the high speed. Two-speed motors are used on elevators having car speeds up to 550 ft. per minute. Higher speed elevators usually require D.C. driving motors. The two-speed squirrel-cage motor is most popular, but the combination motor is suitable for more severe service (greater number of starts and stops per hour).

**Adjustable-speed Brush-shifting Motors** are similar in construction to wound-rotor motors, except that the primary winding is on the rotor, the secondary winding is on the stator, and an additional adjusting winding, connected to a commutator, is provided on the rotor. Power is supplied to the primary winding through collector rings, and the secondary (stator) winding is connected to brushes which bear on the commutator. A means is provided for shifting the brushes around the commutator whereby the speed

† These frame numbers will also apply for 2200-volt motors.

adjustment is obtained. These motors can be obtained with a 3 : 1 or 4 : 1 speed range, the top speed being 135 to 150% of synchronous speed. The motors are limited in rating to about 8 Hp. per pole (60-cycle motors) at the top speed for 3 : 1 speed range, and can be obtained only for low voltage (550 volts and below) power supply. They are constant torque machines, *i.e.*, the horsepower output varies directly with the speed. For any given brush setting, the speed is essentially independent of the load. Though considerably higher in cost than wound-rotor or multi-speed squirrel-cage motors, they have the advantages of a wide speed range with an infinite number of speed points, good efficiency at all speeds, and good speed regulation. Typical applications are textile machinery (cloth calenders and finishing machines, sanforizing machines and cloth-printing machines), stokers, printing presses, small paper machines, and conveyors.

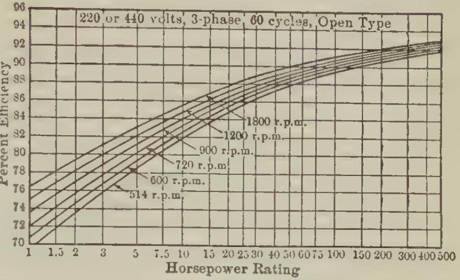

FIG. 13. Approximate Full-load Efficiencies of Class A Squirrel-cage Induction Motors

**Adjustable Varying-speed Brush-shifting Motors** are similar to the adjustable speed machines, except that no adjusting winding is provided; instead, the single rotor winding is connected to a commutator. Brushes bearing on the commutator are supplied with power from the secondary of a transformer whose primary is connected in series with the stator winding. Speed adjustment is obtained by varying the position of the brushes. The motor has varying speed characteristics, the no-load speed being approximately 50% above the full load speed. Capacities up to 15 Hp. per pole at the top speed can be obtained, with a speed range up to 3 : 1. Top speed is about 10% above synchronous speed. Either low- or high-voltage motors can be obtained. In some cases the stator winding is arranged for re-connection from delta to star, when going from the upper part of the speed range to the lower part. Higher efficiency and power-factor thereby are obtained in the lower speed range. These motors have been used largely for driving large fans operating over a wide speed range.

## Operating Characteristics

**TEMPERATURE RISE.**—The temperature rise of standard squirrel-cage (Class A, B, C, or D), wound-rotor, multi-speed, and quiet-operating motors, when operating under rated conditions, is 40° C. rise, measured by thermometer for open motors; 50° C. for splash-proof motors; 55° C. for totally-enclosed motors. Adjustable-speed brush-shifting motors usually are rated 40° C., when operating from maximum full-load speed down to 50% speed. They are rated 50° C. when operating at lower speeds. Open motors rated 40° C. usually are given a *service factor* of 1.15; *i.e.*, manufacturers guarantee successful operation at 1.15 times rated load without injurious heating, although the efficiency and power-factor may be slightly different from the rated load values.

**EFFICIENCY.**—Typical full-load efficiencies and power-factors of standard Class A squirrel-cage induction motors are given in Figs. 13 and 14 respectively. The efficiencies of Class B and Class C squirrel-cage motors and wound-rotor motors are somewhat lower, and those of Class D squirrel-cage motors considerably lower, than those of Class A squirrel-cage motors. The power-factors of Class B and C squirrel-cage motors also are somewhat lower than those of Class A motors. Adjustable-speed brush-shifting motors have efficiencies at the maximum speed slightly lower than

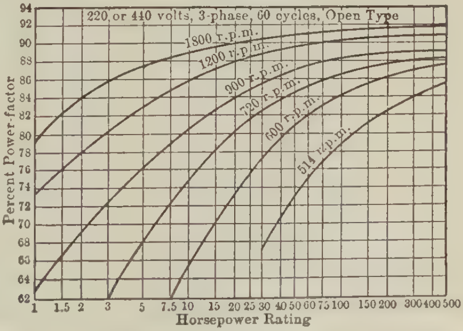

FIG. 14. Approximate Full-load Power Factors of Class A Squirrel-cage Induction Motors

those of wound-rotor motors, but at reduced speeds their efficiencies are considerably higher than those of wound-rotor motors operating at reduced speeds.

**TORQUE AND STARTING CURRENT.**—Minimum starting and breakdown torques and typical starting current of Class A, squirrel-cage motors are given in Table 17. Relative values for the other classes of squirrel-cage motors are indicated by the curves of Figs. 10 and 11.

As shown in Fig. 12, the starting torque and starting current of wound-rotor motors vary over a wide range, depending on the amount of external resistance in the rotor circuit. It is usual to start these motors with sufficient external resistance to give 100% torque and current at standstill, the resistance being short-circuited in steps as the motor comes up to speed. The minimum breakdown torque for wound-rotor motors is 200% of full-load torque.

Adjustable-speed brush-shifting motors usually are started with the brushes in the low-speed position. The starting torque then is 140 to 200% of full-load torque, and the starting current is 125 to 175% of top speed full-load current. Their breakdown torques vary between 140 and 200%, with the brushes in the low-speed position, and are not less than 250% with the brushes in the high-speed position.

**VOLTAGE VARIATION.**—All polyphase induction motors should operate successfully at rated load and frequency at any voltage not more than 10% above or below normal, but not necessarily in accordance with the standards of performance established for operation at normal rating. The starting currents are approximately proportional to the applied voltage, and the starting and breakdown torques are approximately proportional to the square of the voltage.

## Mechanical Features

Large power polyphase induction motors usually are furnished with feet on the stator frame, and end-shield type bearings, although pedestal type bearings, with or without base, may be used in sizes above 1 Hp. per r.p.m. The smaller motors also can be obtained with a machined face on the drive end end-shield, or provided with a flange for bolting to the driven machine. Vertical motors, as well as the standard horizontal motors, can be obtained. The former usually have a ring base, although a four-leg or tripod base can be obtained in the small sizes.

Sleeve bearings, oil-ring-lubricated, are standard for most horizontal machines. Ball bearings are standard on totally-enclosed, and splash-proof motors, and on all but the larger vertical motors. They can be obtained at increased cost on all motors. Ball

(*Continued on page 25–38*).

bearings usually are grease lubricated, although oil lubrication may be used on large high-speed motors and for the thrust bearing of large vertical machines.

Motors which may be belted (flat belt) with two bearings are indicated in Table 16. Sliding bases and pulleys are available. Larger ratings require an extended base and shaft with an outboard bearing. Slide rails usually are supplied for belt adjustment. With multiple V-belt drive, two-bearing construction is suitable for ratings about 25 to 50% larger than with flat belt drive. One manufacturer offers a line of "sound isolating" bases for use with quiet-operating motors arranged for V-belt drive. These prevent or greatly reduce the transmission of motor vibration through the base to the building structure, where it might otherwise be amplified and become exceedingly objectionable. Their use is justified in locations where noise must be kept to a minimum.

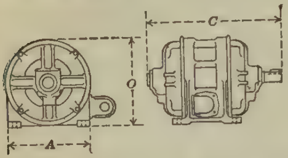

Fig. 15. Approximate Dimensions and Weights of General Purpose Squirrel-cage Induction Motors, Open Type, 60 Cycle

Gear-motors are available in ratings up to about 75 Hp., with output shaft speeds of 13 to 600 r.p.m. High-speed (1800 r.p.m. at 60 cycles) motors of either the squirrel-cage or wound-rotor type are employed.

In addition to the standard open type motors, drip-proof, splash-proof, totally-enclosed, totally-enclosed fan-cooled, and explosion-proof (Class I, Group D or Class II, Group G conditions) motors are available. Totally-enclosed motors are available in sizes up to 5 Hp., and totally-enclosed fan-cooled in sizes up to 400 Hp. (at 1800 r.p.m.). In the larger sizes, enclosed, self-ventilated, or enclosed, separately-ventilated motors must be used where enclosed motors are necessary.

**WEIGHTS AND DIMENSIONS.**—Frame numbers assigned to the various types of continuously rated squirrel-cage and wound-rotor motors are given in Tables 18 to 24 inclusive. Standardized mounting dimensions corresponding to the various frame numbers are given in Tables 14 and 15 and Figs. 7 and 8. Approximate net weights are given in Table 26.

Approximate weights and overall dimensions of squirrel-cage motors built in larger frames than those having standardized dimensions are given in Table 25 and Fig. 15.

**COSTS.**—Approximate 1936 costs of open, horizontal, sleeve-bearing, 60-cycle, squirrel-cage induction motors (Class A) are given in Fig. 16. Other types are more costly, the approximate percentage increase over the cost of Class A motors being as follows: Squirrel-cage, Class B, 0 to 10%; squirrel-cage, Class C, 5 to 15%; squirrel-cage, Class D, 30 to 50%; wound-rotor, 30 to 150%; quiet-operating squirrel-cage, 15%; quiet-operating wound-rotor, 25%.

Special mechanical features increase the cost approximately as follows: Ball bearings, 5%; sliding base, 5 to 15%; pulley, 2 to 5%; splash-proof motors (ball bearing), 7 1/2 to 15% over ball-bearing motor; totally-enclosed fan-cooled (ball bearing), 40 to 80% over ball-bearing motor; explosion proof (Class I, Group D conditions), 50 to 100% over

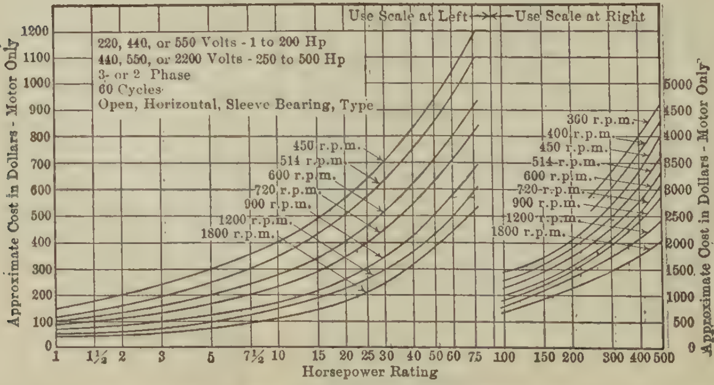

Fig. 16. Approximate 1936 Costs of Open Horizontal Sleeve-bearing 60-cycle Squirrel-cage Induction Motors, Class A

ball-bearing motor; enclosed, separately-ventilated, 20%; enclosed, self-ventilated, 40%; vertical, solid shaft, no thrust, 20 to 40%.

## 5. POLYPHASE SYNCHRONOUS LARGE POWER MOTORS

Standard horsepower and speed ratings of large power, polyphase, synchronous motors are given in Table 27.

**TYPES** in general use are as follows: *a*. High-speed motors; 1. General purpose; 2. Large high-speed. *b*. Low-speed motors; *c*. Special high-torque motors.

**High Speed Motors** are those operating at speeds of 500 r.p.m. or higher. The *general purpose* group includes those rated 200 Hp. or less with speed ratings of 500 to 1800 r.p.m. inclusive. The *large high-speed* group includes motors rated 250 Hp. or more, and all 2 pole ratings. The former have somewhat higher torques (see Table 28), but otherwise both groups have similar characteristics. High-speed synchronous motors have somewhat the same field of application as general purpose squirrel-cage induction motors, but their use is confined largely to ratings of 50 Hp. or above. Except in the large sizes, the synchronous motors are more costly than the induction motors, but their high efficiency and unity or leading power-factor frequently justify their use. Typical applications include: Pumps; motor-generator sets; fans; blowers; reciprocating and centrifugal compressors; rubber mills; line shafts.

**Low-speed Motors** are those operating at speeds of 450 r.p.m. or below. In general, these have lower costs than corresponding ratings of induction motors, as well as higher efficiencies and unity, or leading, power-factor. Typical applications include: Recipro-

* Low speed motor only.

cating compressors; reciprocating, centrifugal and screw type pumps; Jordan engines; ball mills; metal rolling mills; electroplating generators; line shafts.

**High-torque Motors.**—Synchronous motors can be obtained with sufficient starting torque for any application and with moderate starting current. To meet the requirements of high starting torque with very low starting current several special types of synchronous motors are available.

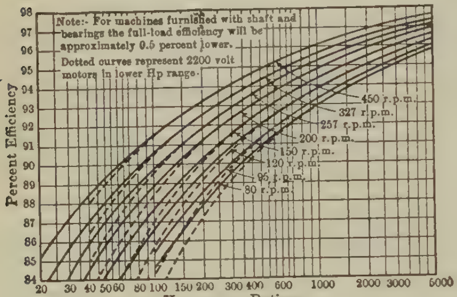

Fig. 17. Approximate Full-load Efficiency of Low-speed Synchronous Motors

The *super-synchronous* motor offered by one manufacturer is of conventional construction except that the stator as well as the rotor is mounted on bearings and a brake is provided which can be applied to prevent the stator from rotating. In starting the motor the brake is released, and the stator comes up to speed in reverse rotation while the rotor and connected load remain stationary. After the motor has been synchronized the brake is applied, gradually bringing the stator to rest, the rotor simultaneously accelerating the load up to speed. Thus the full synchronous pull-out torque of the motor is available for starting the load, and the current drawn from the line, in percent of full-load current, is essentially no greater than the percent starting torque required. Accurate control of the rate of acceleration of the load also is obtained.

The *synchronous induction* motor is essentially a wound-rotor induction motor which starts in the normal manner, but after it is up to speed direct-current excitation is applied to the rotor winding. This causes the motor to pull into step and operate as a synchronous motor. Thus the high starting torque with low starting current of the wound-rotor induction motor is obtained. Disadvantages of this type of motor are that its efficiency is somewhat lower than for other types of synchronous motors, and a high-current, low-voltage exciter is required for excitation.

Synchronous motors with *phase-wound* amortisseur windings are also available. These have the usual salient-pole field, but the amortisseur or starting winding, instead of being of the squirrel-cage type, is insulated, phase-wound and brought out to collector rings through which the circuit may be completed external to the motor. In some cases these motors are built with a revolving armature and a stationary field, eliminating the necessity for collector rings for the field or amortisseur winding, but requiring collector rings for the A.C. armature winding. In either case the motor is started with a high resistance in the amortisseur winding circuit, which is short circuited in steps as the motor comes up to speed. Thus high starting torque with relatively low starting current is obtained.

All of these special types of synchronous motors are considerably more costly than the conventional type, and are justified only in particular applications involving severe starting duty and low starting current.

## Operating Characteristics

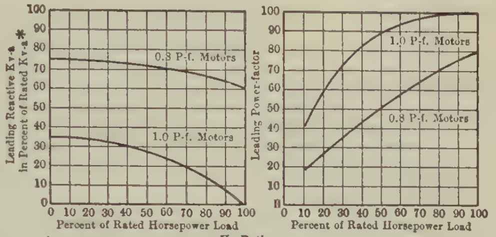
**POWER-FACTOR.**—Standard power-factor ratings of synchronous motors are unity and 0.8 leading, but motors rated at leading power-factors down to 0.2 are available. The unity-power-factor machines are least costly and have the highest efficiency, but the leading power-factor machines often are justified where additional leading kva. is required.

**TEMPERATURE RISE.**—The temperature rise of standard open-type, unity power-factor, high-speed synchronous motors is 40° C., measured by thermometer, for the armature winding, and 50° C., measured by resistance, for the field winding; for leading power-factor, high-speed motors it is 40° C., by thermometer, for the armature winding, and 60° C. by resistance, for the field winding. Splash-proof motors are rated 50° C. rise by thermometer, for the armature winding, and 60° C. rise, by resistance, for the field winding. The temperature rise of standard open-type unity- and 0.8-power-factor, low-speed synchronous motors is 50° C., by thermometer, for the armature winding, and 60° C., by resistance, for the field winding.

Like general purpose induction motors, high-speed synchronous motors rated 40° C.

usually are given a service factor of 15% *i. e.*, they may be operated at 1.15 times rated load without injurious heating.

**EFFICIENCY.**—Typical full-load efficiencies of unity-power-factor high-speed motors are given in Table 28 and of low-speed synchronous motors in Fig. 17. Efficiencies for machines supplied without bearings do not include windage or friction losses. Motors rated 0.8 power-factor have efficiencies ranging from 0.5% to 4% lower than for unity power-factor machines.



*$\text{Rated Kv-a} = 0.746 \times \frac{\text{Hp. Rating}}{\text{Full-load Eff.} \times \text{P-f. Rating}}$

FIG. 18. Power Factor Relations of Synchronous Motors

A synchronous motor operating at full-load with rated excitation delivers *leading reactive kva.* to the power system. The value is determined by

$$\text{kva.} = \frac{0.746 \times \text{Hp. rating}}{\text{Efficiency} \times \text{Power-factor}} \sqrt{1 - (\text{Power-factor})^2}$$

When operating at partial loads, with rated excitation maintained, the power-factor becomes more leading, and more leading kva. is supplied to the system. See Fig. 18.

**TORQUE.**—Minimum values of starting, pull-in, and pull-out torques for general-purpose, large high-speed, and low-speed synchronous motors are given in Table 29. The pull-in torque of a synchronous motor varies with the fly-wheel effect ($WR^2$) of its connected load; the higher the $WR^2$, the lower the load which the motor is capable of pulling into synchronism. The values of pull-in torque given in Table 29 are based on loads having a normal $WR^2$. However, motors with considerably higher starting, pull-in, and pull-out torques can be obtained, though usually at increased cost.

at normal rating. Their starting currents and pull-out torques are approximately proportional to the applied voltage, while their starting and pull-in torques are approximately proportional to the square of the voltage. Their pull-out torques also are approximately proportional to the excitation current.

## Mechanical Features

High-speed synchronous motors usually are furnished with feet on the stator frame and end-shield-type bearings. Pedestal-type bearings, with or without base, may be used in sizes above 1 Hp. per r.p.m. A direct-connected exciter often is supplied. This is overhung on an extension of the motor shaft on the collector ring end (opposite the drive end). The exciter frame is bolted to the corresponding end-shield, or is supported from the base of pedestal bearing machines.

Low-speed synchronous motors commonly are supplied without base, shaft or bearings, the rotor being mounted directly on the shaft of the driven machine. In this case, a completely split rotor spider, or split hub spider, may be supplied to facilitate assembly at the installation. Foundation caps usually are provided for support of the stator frame. A shaft, pedestal-type bearings, and base or sole plates are provided where a self-contained unit is required.

Direct-connected exciters seldom are used with low-speed synchronous motors, since higher speed belt- or motor-driven exciters are more economical.

Sleeve bearings, oil-ring-lubricated are standard for most horizontal synchronous motors, although grease-lubricated ball bearings can be obtained at increased cost. Vertical motors usually are furnished with ball bearings in the smaller sizes, and oil-lubricated plate-type bearings in the larger sizes.

The horsepower limits for two-bearing belt drive are essentially the same as for induction motors (Table 16). Pulleys and sliding bases are available. Vertical synchronous motors, as well as the standard horizontal machines, can be obtained.

In addition to the open motors, drip-proof, splash-proof, totally-enclosed fan-cooled, enclosed self-ventilated, and enclosed separately-ventilated motors are available.

**WEIGHTS AND DIMENSIONS.**—Approximate overall dimensions and net weights of high-speed synchronous motors are given in Table 30 and Fig. 19. Low-speed synchronous motors generally are specially designed for the particular application, with resultant wide variation in weights and dimensions for each rating.

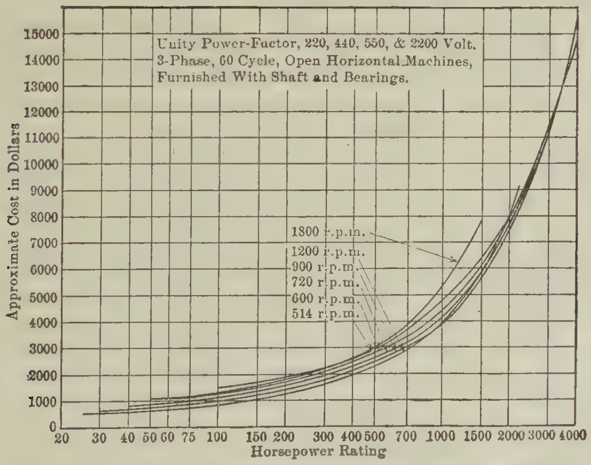

Fig. 20. Approximate 1936 Costs of High-speed Synchronous Motors

**COSTS.**—Approximate costs of open, horizontal, unity-power-factor high-speed synchronous motors, furnished with shaft and two bearings are given in Fig. 20. Special features increase the cost approximately as follows: 0.8 power-factor, 17%; 4000-volt (75 Hp. and larger), 7 1/2 %; 6600-volt (400 Hp. and larger), 17 to 30%; ball bearings, 10%; drip-proof covers, 5%; enclosed self-ventilated construction, 40%; enclosed

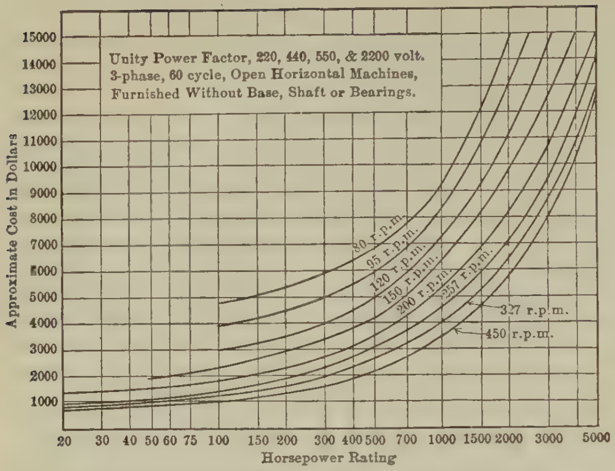

FIG. 21. Approximate Costs of Open, Horizontal, Unity-power-factor, Low-speed Synchronous Motors

separately ventilated construction, 10%; splash proof construction, 15%; totally-enclosed fan-cooled construction, 125 to 150%; vertical construction, 40 to 65%.

Approximate costs of open, horizontal, unity-power-factor low-speed synchronous motors furnished without base, shaft, or bearings, but with foundation caps are given in Fig. 21. Special features increase the cost as follows: 0.8 power-factor, 20%; 4000-volt (75 Hp. and larger), 5 to 10%; 6600-volt (400 Hp. and larger), 17 to 30%; split rotor, 2 to 5%; split stator, 7 1/2 to 15%; shaft and two bearings, 30%; base, shaft, and two bearings, 35%; ball bearings, 10%; splash-proof construction, 15%; vertical construction, 70%.

## 6. DIRECT-CURRENT LARGE POWER MOTORS

The following types of large power, direct-current motors are in general use:

*a.* General purpose constant speed motors; *b.* Adjustable speed motor; *c.* Large direct-current motors; *d.* Fan motors; *e.* Crane and hoist motors; *f.* Mill-type motors; *g.* Metal rolling mill motors; *h.* Elevator motors; *i.* Low-speed, engine-type motors.

**General Purpose Motors.**—Standard horsepower and speed ratings for general purpose constant speed motors are given in Table 31. These motors are available with shunt, series, or compound-wound field windings. The shunt-wound motors have the lowest speed regulation (change in speed with change in load), are lowest in cost and have the

| 200 | .... | 1750 | 1150 | 850 | 690 | 575 | 500 | 450 | 400 | 350 | 300 | 250 | 200 | 150 | 100 |

widest application. The compound-wound motors have somewhat higher speed regulation, and are used on loads requiring high starting torque, and on those subject to torque pulsation. Series-wound motors have very high speed regulation, and should not be used with belt drive or on any load in which the torque might drop below 15% of full-load torque, since a dangerously high speed would be developed. Series motors are used on loads requiring a very high starting torque or severe accelerating duty, and where high speed regulation is advantageous or of no consequence.

Shunt-wound constant speed motors, having a full load speed of 1750 r.p.m. or below, usually can be operated at some increase in speed, without increase in horsepower, by inserting a resistance in series with the field winding. The maximum increase in speed permissible varies from about 10% for the higher speed ratings to 100% for the lower speed ratings. Speed variation by shunt field control generally is not advisable on compound-wound motors, since, with a weakened field, the motor characteristics approach those of a series motor and high speed regulation results.

**Adjustable Speed Motors** are shunt-wound machines, designed particularly for adjustable speed operation by varying the strength of the shunt field. Standard horsepower and basic (minimum) speed ratings are the same as for the constant speed motors (Table 31). Speed ranges (ratio of maximum speed to basic speed) of 3 : 1 and 4 : 1 are standard, although motors having a speed range of 6 : 1 can be obtained at increased cost. In any case, the maximum speed usually is limited to the values shown in Table 32. Three different horsepower ratings may be given to adjustable speed motors: 1. A standard continuous horsepower rating over entire speed range, with a temperature rise of 50° C. from basic speed to 150% of basic speed, and a temperature rise of 40° C. from 150% of basic speed to the maximum speed. 2. A standard intermittent horsepower rating over the entire speed range, with a temperature rise of 50° C. in 1 hour. 3. A *tapered rating* consisting of a certain standard horsepower from basic speed to 150% of basic speed, the next larger standard horsepower at 3 times basic speed and higher, and a horsepower varying along a straight line from the lower value to the upper value as the speed varies from 150% of basic speed to 3 times basic speed. The temperature rise is 50° C. continuous from basic speed to 150% of basic speed, and 40° C. continuous from 150% of basic speed to maximum speed.

In general, a motor rated in accordance with [1] will have the same cost as a motor of the next larger horsepower rated in accordance with [2], and the same cost as a tapered rating motor whose lower horsepower is the same. Adjustable speed D.C. motors are used most extensively on machine tools.

**Large D.C. Motors.**—Standard horsepower rating of these motors are as follows: 250, 300, 350, 400, 500, 600, 700, 800, 900.

Standard speed ratings, in r.p.m., are: 1150, 850, 690, 575, 500, 450, 400, 350, 300, 250, 225, 200, 175, 150, 125, 110, 100. These speed ratings apply to all standard sizes of large D.C. motors, excepting that 500 Hp. is the largest size to which the 1150 r.p.m. rating applies. These motors may be constant speed or adjustable speed (constant horsepower). The maximum speed range varies from 5 : 1 for the smaller and lower speed ratings, to about 1 1/2 : 1 for the larger and higher speed ratings. Typical applications include pumps, fans, rubber mills and paper mills.

**Crane and Hoist Motors** normally are series-wound, totally-enclosed machines, and are rated 15 minutes, 55° C. temperature rise, or 30 minutes, 55° C. rise. Standard ratings range from 1 to 50 Hp. at speeds of 500 to 1500 r.p.m. Shaft extensions at both ends, for brake and drive, respectively, and pinion, gear and reduced speed axle mounted integrally with the motor are features available. Although higher in cost than standard motors, their compactness, rugged mechanical construction, and low-inertia armature justifies their use on cranes, hoists, and similar loads involving intermittent service and severe reversing duty.

**Table 32.—Maximum Speed by Field Control of Shunt-wound Adjustable Speed D.C. Motors**

| Continuous Hp. Rating | * Maximum Speed, r.p.m. | Continuous Hp. Rating | * Maximum Speed, r.p.m. | Continuous Hp. Rating | *Maximum Speed, r.p.m. | Continuous Hp. Rating | * Maximum Speed, r.p.m. |
|---|---|---|---|---|---|---|---|
| 1/2 | 3450 | 3 | 2300–2500 | 20 | 1500–1800 | 60 | 1200–1500 |
| 3/4 | 3450 | 5 | 2000–2300 | 25 | 1500–1800 | 75 | 1200 |
| 1 | 2500–2875 | 7 1/2 | 2000–2300 | 30 | 1200–1800 | 100 | 1200 |
| 1 1/2 | 2500–2875 | 10 | 1800–2300 | 40 | 1200–1600 | 125 | 1200 |
| 2 | 2500–2875 | 15 | 1500–1800 | 50 | 1200–1500 | 150 | 1200 |

* Maximum speed also is limited to six times the basic (minimum) speed rating.

**Fan Motors** are shunt-wound machines suitable for direct connection to centrifugal fans. The standard horsepower ratings are 1/2, 3/4, 1, 1 1/2, 2, 3, 5, 7 1/2, 10, 15, 20, 25, 30, 40 and 50. Standard speed ratings for both the constant speed and adjustable speed motors are given in Table 33. In the case of the adjustable speed machines, the normal horsepower rating corresponds to that obtained at maximum speed (weakened field). At the minimum speed (full field), it is assumed that the horsepower will be reduced in proportion to the cube of the reduction in speed.

* Standard speed ratings of constant speed fan motors.
† Corresponding speed rating of constant speed motor is 575 r.p.m.

**Mill-type Motors** are heavy duty machines, designed particularly for such service as steel mill auxiliaries, electric power shovels, and cranes. The basic motor is series-wound, totally-enclosed, intermittently rated 1 hour, 75° C. temperature rise with horsepower and speed ratings as shown in Table 34. The ratings from 7 1/2 to 75 Hp. inclusive have been standardized by the A.I.S.E.E. with standardized shaft, mounting dimensions, and other features. In addition to the basic motor, shunt- and compound-wound, open, semi-enclosed, and enclosed forced ventilated, 1/2 hour and continuous rated motors are available. In general the horsepower and speed ratings for such motors differ from those of the basic motors. All motors have Class B insulation, roller or double-row ball bearings, and shaft extensions on both ends. A pinion, gear and reduced speed axle with sleeve or roller bearings also can be obtained. Rugged mechanical construction, low-inertia armatures, compactness, and accessibility of all parts are features of these motors.

**Metal Rolling-mill Motors** are large, heavy-duty machines, designed for metal rolling mill drive. Standard horsepower and speed ratings are given in Table 35. The motors are arranged for adjustable speed operation by shunt field control. The standard speed range varies from about 1.5 : 1 to 2 : 1, depending on the horsepower and basic speed rating. However, speed ranges up to 5 : 1 can be obtained in some cases, though at higher cost. The motors normally are furnished with base and pedestal type bearings.

### Table 35.—Standard Horsepower and Speed Ratings of Adjustable Speed Metal Rolling Mill D.C. Motors

| Standard Basic-Speed Ratings, r.p.m. |
|---|
| 1150, 850, 690, 575, 500, 450, 400, 350, 300, 250, 225, 200, 175, 150, 125, 110, 100, 90, 80, 70, 65, 60, 55, 50 |

Standard Horsepower Ratings

| Hp. | Basic Speeds, r.p.m. | Hp. | Basic Speeds, r.p.m. | Hp. | Basic Speeds, r.p.m. |
|---|---|---|---|---|---|
| 250 | 100 to 1150 | 800 | 60 to 850 | 2250 | 50 to 350 |
| 300 | 100 to 1150 | 900 | 55 to 850 | 2500 | 50 to 350 |
| 350 | 100 to 1150 | 1000 | 50 to 850 | 3000 | 50 to 300 |

| 600 | 80 to 850 | 1750 | 50 to 500 | 4500 | 50 to 200 |
| 700 | 70 to 850 | 2000 | 50 to 400 | 5000 | 50 to 175 |

**Geared Elevator Hoisting Machines** employ high-speed motors similar to the general purpose motors. They usually are adjustable speed machines, with shunt field control or variable armature voltage control. Gearless elevators require a special low-speed driving motor. The hoisting drum is mounted on the motor shaft between the two bearings. A brake wheel for a solenoid brake usually is cast integrally with the drum. Heavy shafts and large bearings are provided. The motors are of the adjustable speed type with armature voltage control.

**Low-speed Engine-type D.C. Motors** are available in ratings from 100 to 250 Hp., at speeds of 150 to 327 r.p.m. The standard speeds are the same as for low-speed, 60-cycle, synchronous motors (Table 27). The motors are compound-wound, and are furnished without base, shaft, or bearings. They are used to drive low-speed machines, such as reciprocating compressors, the rotor being mounted on the shaft of the driven machine.

## Operating Characteristics

**TEMPERATURE RISE** of standard general purpose motors is 40° C., measured by thermometer for open motors, 50° C. for semi-enclosed, drip-proof, and splash-proof machines, and 55° C. for totally-enclosed and totally-enclosed fan-cooled machines. Open motors rated 40° C. usually are given a service factor of 1.15; that is, the manufacturers guarantee successful operation at 1.15 times rated load without injurious heating. D.C. motors generally are capable of delivering 50% overload in torque momentarily, without temperature guarantee.

**EFFICIENCY.**—Typical approximate full-load efficiencies of general purpose, constant-speed shunt-wound open-type motors are given in Fig. 22.

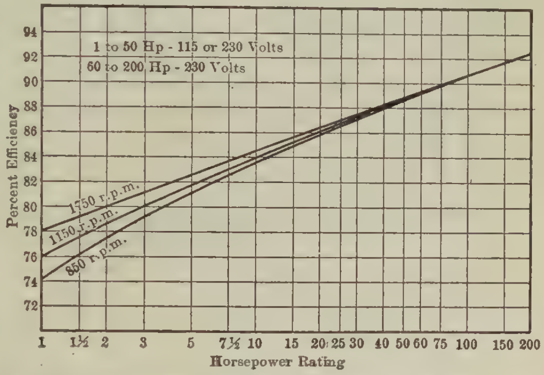

Fig. 22. Approximate Full-load Efficiency of General Purpose Constant-speed Shunt-wound Direct-current Motors, Open Type

**TORQUE.**—With full voltage on the shunt field (if provided), and with the armature current limited to full-load current the starting torque of any type of D.C. motor is 100% of full-load torque. For shunt-wound motors the starting torque will vary directly with the armature current; for series-wound motors, it varies approximately as the square of the armature current; for compound-wound motors the variation lies between these two limits, depending on the ratio of shunt and series windings. The armature current, in turn, is determined by the amount of resistance inserted in series with this winding at start. Standard starters usually limit the current to from 125 to 200% of full load current.

**SPEED REGULATION** from full load to no load, hot, based on full load speed should not exceed the following:

Constant-speed motors, shunt-wound: 5 Hp. and smaller, 12%; 7 1/2 to 200 Hp. inclusive, 10%; 250 Hp. and larger, 6%; Compound-wound, constant-speed motors, 25%.

Adjustable speed motors, shunt-wound: 2 to 5 Hp. inclusive, 22%; 7 1/2 to 200 Hp. inclusive, 15%; 250 Hp. and larger, at maximum speed, 4%; at basic speed, 6 to 15%.

At normal operating temperature, rated load and voltage, the variation above or below rated speed should not exceed the following:

Constant-speed motors, shunt- or compound-wound, 7 1/2 Hp. at 1150 r.p.m. or smaller, 7 1/2 %; larger than 7 1/2 Hp. at 1150 r.p.m., 5%.

Adjustable-speed motors, shunt-wound, 5 Hp., 650 r.p.m. (minimum speed) or smaller, 7 1/2 %; larger than 5 Hp., 650 r.p.m., 5%.

The variation in speed from full load, cold, to full load, hot, should not exceed 10%, based on full-load speed.

**VOLTAGE VARIATION.**—All D.C. motors should operate successfully at normal rated load at any voltage not more than 10% above or below normal, but not necessarily in accordance with the standards of performance established for operation at normal rated voltage. In general, with a given load, an increase in voltage results in an increase in speed and *vice versa.*

Any shunt-wound motor may be operated as an adjustable speed machine by maintaining constant voltage on the shunt field while varying the voltage on the armature.

### Table 36.—Frame Sizes for General Purpose Constant Speed D.C. Motors

Open Type

| Speed, r.p.m. | Horsepower 1/2 | 3/4 | 1 | 1 1/2 | 2 | 3 | 5 | 7 1/2 |
|---|---|---|---|---|---|---|---|---|

| 1750 | ........ | .......... | 204 | 224 | 225 | 225 | 254 | 284 |
| 1150 | ........ | 204 | 204 | 224 | 225 | 254 | 284 | ....... |
| 850 | 204 | 224 | 225 | 254 | 254 | 284 | .......... | ....... |

* See Tables 14 and 15, and Figs. 7 and 8 for standard mounting dimensions.

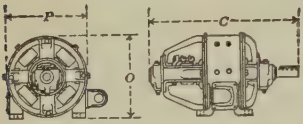

FIG. 23. Dimensions General Purpose Constant-speed Direct-current Motors. See Table 37

The speed will be approximately proportional to the armature voltage. The basic speed of such a machine is the maximum speed (full voltage on the armature). At reduced speeds, the horsepower is reduced approximately in proportion to the speed. Thus *variable voltage control* gives constant torque characteristics, as contrasted with speed variation by field control which gives essentially constant horsepower characteristics. Where the source of variable voltage direct current is such that the voltage provided is essentially independent of the current drawn, the motor is truly an adjustable speed machine, *i.e.*, its speed when once adjusted to given value remains essentially constant,

**Table 38.—Approximate Weights of D.C. Motors Built in N.E.M.A. Standardized Frames**

| Frame No. | Open Motors | Totally-enclosed, Fan-cooled Motors | Base | Pulley |
|---|---|---|---|---|
| | Approximate Weight, lb. | | | |
| 204 | 105 | ... | 20 | 1 |
| 224 | 150 | 160 | 25 | 3 |
| 225 | 160 | 170 | 25 | 3 |
| 254 | 210 | 225 | 30 | 4 |
| 284 | 280 | 300 | 35 | 5 |

regardless of the load. A D.C. generator, driven at constant speed with voltage variation by field control, meets this requirement and commonly is used. On the other hand, if the applied armature voltage varies appreciably with the current drawn, as would be the case if a variable resistance were used to reduce the voltage, the drive would be of the adjustable varying speed type, *i.e.*, the speed varies appreciably with the load.

## Mechanical Features

Large power D.C. motors usually have feet on the stator frame and end-shield-type bearings, in sizes up to about 200 Hp. In the larger sizes, a base with pedestal-type bearings usually is supplied. Vertical motors, as well as the standard horizontal motors, can be obtained.

Sleeve bearings, oil-ring-lubricated, are standard for most horizontal machines. Ball bearings are standard on totally-enclosed, splash-proof, and the smaller vertical motors. They can be obtained at increased cost on all motors. Ball bearings usually are grease lubricated.

Motors which may be belted (flat belt) with two bearings are indicated in Table 31. Sliding bases and pulleys are available. Larger ratings require an extended base and shaft with outboard bearing. Slide rails usually are supplied for belt adjustment. With multiple V-belt drive, 2-bearing construction is suitable for ratings from 25 to 50% larger than with flat belt drive.

Gear-motors are generally available in sizes up to 7 1/2 Hp., with output shaft speeds of 13 to 600 r.p.m. High-speed (1750 r.p.m.) motors are employed.

In addition to the standard open type motors, drip-proof, splash-proof, totally-enclosed, totally-enclosed fan-cooled, and explosion-proof (Class I, Group D or Class II, Group G conditions) motors are available.

**WEIGHTS AND DIMENSIONS.**—Frame numbers assigned to general-purpose constant-speed D.C. motors are given in Table 36. Approximate weights and overall dimensions of general-purpose constant-speed motors built in larger frames than those having standardized dimensions are given in Table 37 and Fig. 23. Approximate net weights are given in Table 38.

**COSTS.**—Approximate costs of open, horizontal, sleeve-bearing, shunt-wound general-purpose, constant speed D.C. motors are given in Fig. 24. Adjustable speed motors have approximately the same cost as constant-speed motors, based on the continuous constant horsepower and basic speed ratings of the adjustable-speed machine. Approximate costs of other types can be determined from the following percentage increases in cost over standard constant-speed motors: Series- or compound-wound, 4%; quiet operating, 25%.

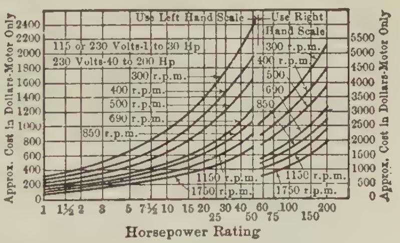

Fig. 24. Approximate 1936 Costs of General Purpose, Constant-speed, Shunt-wound, Direct-current Motors

Special mechanical features increase the cost approximately as follows: Ball bearings, 5%; sliding base, 2–5%; pulley, 1–3%; drip-proof construction, 4%; splash-proof construction, 12%; totally-enclosed fan-cooled construction, 50–100%; vertical construction, 20%.

## 7. MOTOR APPLICATIONS

The types of motors commonly used on various applications are given in Table 39. The items listed in the table are those of general application, for which conditions generally are well standardized. It is not possible to list the diverse application where motors operate under unusual conditions. Since many factors affecting the choice of motor vary with each individual installation, the recommendations given should be considered typical and not necessarily applying in every case. Manufacturers of motors should be consulted with reference to the selection of the proper motor for unusual or non-standard conditions.

**Table 39.—Types of Motors Commonly Used for Various Applications**

Wr. = wound rotor.

# ELECTRIC MOTOR CONTROL

## 1. GENERAL

**FUNCTIONS.**—The basic function of all motor control is to provide a means for making and breaking the connections between the motor windings and the power lines, thereby starting and stopping the motor. Practically all controllers also provide overload protection for the motor. As will be described, many other functions are provided by certain types of control.

**CLASSIFICATION.** — Motor controllers may be classified as: *a.* Full-voltage controllers; *b.* Reduced-voltage controllers. The former connect the motor directly to the power lines, that is, provide full voltage at the motor terminals during the starting period, as well as for running. The latter connect the motor to a voltage-reducing device during the starting period, and, after the motor has come up to speed, transfer the connections to the power lines. Auto-transformers commonly are used to obtain the reduced voltage in A.C. motor starters, although resistors and reactors frequently are employed. Resistors always are used for this purpose in D.C. motor starters. Full-voltage controllers are the simplest and least expensive, but reduced-voltage controllers often are required to limit the current drawn from the power lines at start.

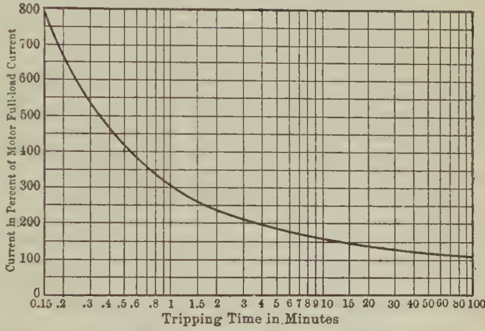

FIG. 1. Tripping Characteristics of Typical Temperature-Overload Relay

Motor controllers also may be classified according to the degree of automatic operation provided. On this basis, there are three standard types: *a.* Manual controllers; *b.* Magnetic controllers; *c.* Semi-magnetic controllers. In Type *a*, all connections to the motor are made by hand-operated switches. In Type *b* controllers, the switches are electrically operated. To start the motor it is only necessary to close a pilot circuit by means of a push button, thermostat, or similar device which may be located at some distance from the controller. Reduced-voltage magnetic controllers are provided with a relay which automatically effects the transfer from starting to running connections. In Type *c* controllers, part of the starting operation is performed by hand-operated switches and the remainder by electrically-operated devices.

**LINE SWITCHES** on low-voltage controllers (600 volts and below) usually are of the *air-break* type, *i.e.*, the circuit is broken in air. Oil-immersed switches usually are employed for the higher voltages. However, where excessive moisture or corrosive agents are present in the atmosphere, the switches, and in some cases the complete equipment, may be oil-immersed, even though controlling low voltage. Electromagnets, either solenoid or clapper type, usually are employed to close electrically-operated switches, although pilot motor-operating mechanisms sometimes are used on oil circuit breakers.

**OVERLOAD PROTECTION.—Thermal Type Overload Relays** usually are used. The most common form consists of a heater element which carries line current (or a current proportional to line current, obtained through a current transformer) mounted adjacent to a bimetallic strip. An overload on the motor causes an increase in line current, which increases the temperature of the heater element. The heat radiated to the bimetallic strip causes it to deflect and open a contact which disconnects the motor from the line. The time required for the relay to trip varies inversely with the magnitude of the overload, as does the length of time the motor can operate without injurious heating. With proper design, the relay will follow closely the heating characteristics of the motor. It thus adequately protects the motor and yet will not take it off the line unnecessarily (see Fig. 1). After the relay has tripped, it must be allowed to cool before it can be reset and the motor restarted. This also allows the motor to cool.

Another form of thermal overload relay, used on small motor starters, is the *solder-film* type. In this, the tripping mechanism normally is held to a stationary element by a thin film of solder. The heater which carries line current will, on an overload of sufficient duration, melt the solder film, thus releasing the tripping mechanism. After tripping, the solder cools and solidifies, allowing the tripping mechanism to be reset.

**Non-thermal Overload Relays** also are used. These incorporate a time delay feature, as an oil or air dashpot, to vary the tripping time with the magnitude of the overload. A disadvantage of this type is that when once tripped they can be reset immediately, and the motor started before it has had time to cool off.

**Fuses.**—Ordinary fuses do not, in general, give satisfactory overload protection. Their time lag is so short that they usually must be selected oversize to prevent tripping on the starting current of the motor, or on high overloads of short duration; as a result they do not give adequate protection against moderate overloads of long duration.

**Relay Resets.**—Most overload relays are of the "hand-reset" type; that is, after tripping they must be reset manually before the motor again can be started. In a few applications, particularly those in which the motor starts and stops automatically (for example, in response to a thermostat), it may be desirable to use an automatically reset overload relay which resets itself after a time delay of sufficient duration to permit the motor to cool. Relays of this type are available for small motors. They frequently are mounted on the motor itself and, in the case of fractional-horsepower, single-phase motors, may be designed to open directly the power circuit to the motor.

Two overload relay elements placed in different phases normally are used with 3-phase and 2-phase motors, while a single element is used with single-phase and D.C. motors.

**UNDER-VOLTAGE PROTECTION AND RELEASE.**—Most controllers are so arranged that on failure of line voltage the circuit to the motor is opened. Manual starters for small motors are an exception. If the line switch is held in the closed position by a magnet energized from the line, this feature is obtained automatically. Where the line switch is held closed by a mechanical latch, an *under-voltage device* must be provided. This is energized from the line, and, on being de-energized, operates to trip the latch. If the control is so arranged that on return of voltage the line switch recloses, *under-voltage release* is obtained. On the other hand if the line switch does not reclose on return of voltage, *under-voltage protection* is obtained. The latter is most common. The former should be used only where there is no hazard involved in the motor starting unexpectedly after a voltage failure.

In many cases, voltage failures are of very short duration, *viz.*, 1 $^1/_2$ seconds or less. Thus it is often desirable to provide control that will restart the motor if the voltage failure does not last over a certain predetermined time, but which will disconnect it permanently if the voltage failure is of longer duration. Control so arranged provides *time delay under-voltage protection*. If the line switch is held closed by a magnet energized from the line, a time delay push button station usually is used. This is so arranged that its contacts are held closed for a definite time (1 to 4 seconds) after a failure of voltage, but can be opened instantaneously by the *stop* button. When the line switch is held closed by a mechanical latch, an under-voltage tripping mechanism which incorporates a time delay in its action must be provided.

**SHORT-CIRCUIT PROTECTION.**—In general, motor controllers should not be expected to interrupt the heavy current which may flow in the event of a short circuit. Either fuses or a circuit breaker of suitable interrupting capacity should be provided for this purpose. These are usually placed in the motor branch circuit at the point where it is connected to the feeder circuit, thus serving also as a branch circuit protective device.

Controllers with high interrupting capacity contactors, or circuit breakers for line switches, are available for use where high interrupting capacity is required. An instantaneous over-current relay or trip coils should be provided, in addition to the overload relay, to insure immediate opening on short-circuit current.

**ENCLOSURES.**—Open type controllers (no enclosing case) are used where they are under competent supervision and installed where accessible only to authorized persons. In any case, all switches and devices whose voltage rating is in excess of 600 volts should be mounted on the back of the panel, or suitably enclosed to prevent accidental contact.

Controllers for small motors almost always are enclosed, and enclosures can be obtained for all sizes. A number of different types of enclosure are available. The standard *general-purpose enclosure* most commonly used is designed primarily to protect against accidental contact; it also protects against dust and light indirect splashing, but it is not dust-tight. It usually is of sheet metal construction. The *drip-tight enclosure* is similar to the general-purpose type with the addition of drip shields, or their equivalent. It is used for applications where condensation may be severe as in cooling rooms and laundries.

*Weather-resisting Enclosures* are of cast construction, or of sheet metal of suitable rigidity, with proper protection against weather hazards, as rain and sleet. They are suitable for outdoor applications as on docks, canal locks, and construction work, and also for applications in subways and tunnels. A *water-tight enclosure* is so designed that a stream of water from a hose (not less than 1 in. diameter) under a head of 35 ft. can be played on the case from a distance of 10 ft. for several minutes without leakage. It is used for outdoor applications and in dairies, breweries, and similar locations. *Submersible enclosures* are so designed that they may be submerged in water as in quarries, mines, and manholes. *Dust-tight enclosures* are provided with gaskets or their equivalent to exclude dust, and are used in such situations as often occur in steel and cement mills.

Controllers for Class I, Group D, hazardous locations (see p. 25–17) may be of the air-break or oil-immersed type. Air-break controllers depend on the strength of the enclosing case to resist the force of an internal explosion, and on long, close fits at all joints to cool the flame and prevent ignition of the surrounding atmosphere. In oil-immersed controllers, all contacts and connections are immersed in oil to prevent ignition of the surrounding atmosphere. This construction is preferable where the control is placed in a corrosive atmosphere. Controllers for Class II, Group G, conditions, and others designed to meet the requirements of the U. S. Bureau of Mines, also are available.

**Combination Switches** consist of a full-voltage magnetic starter combined with a manually-operated motor circuit switch (fused or unfused), or a circuit breaker, mounted in a single enclosing case. Thus, there are provided means for disconnecting the motor and starter, and (with fuses or circuit breaker) protection against short-circuits in the starter, motor, or wiring on the motor side of the switch. General-purpose, dust-tight and water-tight enclosing cases are available. Oil-immersed switches suitable for corrosive atmospheres, or for Class I, Group D, hazardous locations, also can be obtained. Frequently, a saving in space and in installation expense is obtained by the use of a combination magnetic switch, instead of the two separate devices. The former are available in ratings up to 25 Hp. at 220 volts, and 50 Hp. at 440 or 550 volts.

**LOCATION.**—In general, controllers should be placed within sight of the motor which they control. If this is not feasible, the controller or disconnecting device should be provided with means for locking it in the open position; or a manually operated switch, which will prevent restarting, should be placed within sight of the motor. This switch may be located in the pilot circuit of the controller.

## 2. CONTROL FOR SINGLE-PHASE MOTORS

**TYPES.**—The following types of control for single-phase motors are in common use: *a.* Manual full-voltage; *b.* Magnetic full-voltage; *c.* Manual reduced-voltage; *d.* Adjustable speed (for capacitor motors) *e.* Reversing.

**Manual Full-voltage Controllers** are available in sizes up to 1 $^1/_2$ Hp. at 110 volts, 3 Hp. at 220 volts, and 5 Hp. at 440 and 550 volts. They consist of a single- or double-pole line switch, and an overload relay, usually of the solder-film type, mounted on a compound base. They may be obtained open, or enclosed in a sheet metal case. Explosion-proof enclosures, with air-break switches, for Class I, Group D, conditions also are available. The smaller size controllers ($^3/_4$ Hp. and below) usually are arranged so they can be flush mounted, using a sectional switch box and tumbler switch flush plate. Small single-phase motors ($^3/_4$ Hp. and below) can be obtained with a tumbler switch mounted on the motor to serve as a starter. These do not provide overload protection, and should not be used where the switch may be called upon to interrupt the stalled current of the motor.

Manual, full-voltage controllers are the lowest in cost of all types and are used where full-voltage starting is acceptable, and remote control or automatic operation is not required. They do not provide under-voltage protection.

**Magnetic Full-voltage Controllers** are available in sizes up to 7 $^1/_2$ Hp. at 110 volts, 15 Hp. at 220 volts, and 25 Hp. at 440 and 550 volts. They consist of a magnetic contactor mounted on a compound base. A thermal type overload relay usually is provided in sizes above 1 Hp. at 110 volts and 1 $^1/_2$ Hp. at 220 volts. Various types of enclosures are available, including general purpose, dust-tight, water-tight, and explosion-proof for Class I, Group D conditions (both air break and oil-immersed). In the smaller sizes, enclosing cases with start-stop push buttons in the cover can be obtained. Otherwise, a separately-mounted push button station, either instantaneous or time-delay type, must be used. These are also available with general-purpose, dust-tight, water-tight, and explosion-proof enclosures. Frequently a thermostat, pressure switch or similar device is used for pilot circuit control, providing under-voltage release.

Since full-voltage starting of single-phase motors generally is acceptable, and remote or automatic control often is necessary, full-voltage magnetic starters have a wide field of application covering practically all types of drive.

**Manual Reduced-voltage Controllers** consist of a rheostat, which at start is inserted in series with the motor winding, thus limiting the current drawn from the line. As the motor comes up to speed, the operating handle of the rheostat is turned, which short-circuits the resistance step by step, until the motor is on full voltage. A magnet, whose coil is energized from the line voltage, holds the operating handle in the running position. If voltage fails, the handle is released and the motor is disconnected from the line. Overload protection ordinarily is not included. Manual reduced-voltage starters usually are provided with a general-purpose enclosing case. They are used only when the full-voltage starting current of the motor would cause objectionable voltage disturbance. Since the starting torque of the motor is reduced in proportion to the square of the current drawn, it is apparent that a reduction in the current drawn from the line will be obtained only if the load does not require the full-voltage torque of the motor to start.

**Adjustable Speed Controllers** for capacitor motors usually consist of an auto-transformer provided with reduced voltage taps, with a suitable switch for connecting the motor to any one of two or three taps, giving a corresponding number of motor speeds. A manual snap switch may be used in sizes up to 1 Hp. The magnetic type, employing contactors and a push-button station, is available in sizes up to 10 Hp.

**Reversing Controllers** usually are of the full-voltage type. Manually-operated drum or cam-switches are available for this service, in sizes up to 1 $^1/_2$ Hp. at 110 volts, 3 Hp. at 220 volts, and 5 Hp. at 440 or 550 volts. These controllers do not provide overload or undervoltage protection. Magnetic reversing switches are available in sizes up to 3 Hp. at 110 volts, 7 $^1/_2$ Hp. at 220 volts, and 10 Hp. at 440 and 550 volts. They consist of two magnetic contactors, mechanically interlocked to prevent closing of both at the same time. Both overload and under-voltage protection is provided. A 3-button push-button station is required. Enclosing cases of the general purpose type usually are provided, although water-tight and dust-tight enclosing cases also are available.

**COST.**—The approximate 1936 cost of manual, full-voltage controllers ranges from \$3 for the $^3/_4$-Hp. controller, to \$8 for the 1 $^1/_2$-Hp. controller, 110 volts, and from \$3 for the $^3/_4$-Hp. controller to \$8 for the 3-Hp. controller, 220 volts. For magnetic full-voltage type controllers, costs, which include a separately mounted start-stop push-button station, range from \$12 for the $^3/_4$-Hp. controller to \$52 for the 7 $^1/_2$-Hp. controller, 110 volts, and from \$12 for the $^3/_4$-Hp. controller to \$52 for the 15-Hp. controller, 220 volts.

## 3. CONTROL FOR POLYPHASE INDUCTION MOTORS

**TYPES.**—The following types of control for polyphase induction motors are in general use:

**Squirrel-cage Induction Motors.**—*a.* Manual full-voltage; *b.* Magnetic full-voltage; *c.* Manual reduced-voltage (auto-transformer type); *d.* Manual reduced-voltage (resistor type); *e.* Magnetic reduced-voltage (auto-transformer type); *f.* Magnetic reduced-voltage (resistor type); *g.* Multi-speed; *h.* Reversing.

**Wound-rotor Induction Motors.**—*a.* Manual primary and secondary; *b.* Magnetic primary, manual secondary; *c.* Magnetic primary and secondary.

### Squirrel-Cage Motors

**Manual Full-voltage Controllers** of the air-break type for squirrel-cage induction motors are available in sizes up to 5 Hp. at 220 volts, and 7 $^1/_2$ Hp. at 440 and 550 volts. They consist of a manually-operated switch and a 2-element, thermal type, overload relay, mounted in an enclosing case. Under-voltage protection is not provided.

Standard enclosing cases are of the general-purpose type, but explosion-proof cases for Class I, Group D conditions also are available.

Oil circuit breaker type manual full-voltage controllers are available in all sizes. These can be obtained with both overload and under-voltage protection. Except in the very large sizes, they are, in general, more costly than magnetic contactor type controllers. They are used mainly where high current-interrupting capacity is required.

**Magnetic Full-voltage Controllers** are available in all sizes. They are the most popular of all types. The common form consists of a magnetic contactor combined with a thermal type overload relay mounted in an enclosing case. (The air-break type is used for voltages of 600 and below, and the oil-immersed type for higher voltages.) A start-stop push-button station, or similar device, for closing and opening the pilot circuit also is required. Enclosing cases of the general-purpose, dust-tight, and water-tight type are available. Explosion-proof controllers for Class I, Group D, conditions are available in both the air-break and oil-immersed types. In sizes up to 5 Hp. at 220 volts, and 7 $^1/_2$ Hp. at 440 and 550 volts, enclosing cases of the general-purpose, dust-tight or water-tight, and explosion proof (air-break) type, with start-stop push buttons mounted in the cover, are available.

Some manufacturers offer oil-immersed, full-voltage magnetic controllers for high-voltage motors (2200 to 4600 volts) with an interrupting capacity of 50,000 kva. These usually are provided with instantaneous over-current trips, in addition to an overload relay, giving rapid opening on short circuit current. Oil circuit breaker controllers, with whatever interrupting capacity is required, are available in all sizes.

**Manual Reduced-voltage Auto-transformer Controllers** are available in sizes up to 150 Hp. at 220 volts, 300 Hp. at 440 and 550 volts, 800 Hp. at 2000 to 2500 volts, and 900 Hp. at 2501 to 6600 volts. They consist of an auto-transformer with two or three sets of low voltage taps and an oil-immersed double-throw manually-operated switch. In starting, the operating handle is first moved in one direction connecting the motor to a set of reduced-voltage taps of the auto-transformer and held in that position until the motor has come up to speed, after which the handle is moved quickly in the opposite direction to connect the motor directly to the line. The operating handle usually is interlocked mechanically, so that it must be moved to the start position before it can be moved to the run position. Overload and under-voltage (instantaneous or time-delay) protection are provided. General-purpose enclosing cases are standard, but dust-tight cases also are available.

The manual auto-transformer type starters are, in general, the least costly of the various reduced-voltage types. They are used whenever manual control is acceptable, and a reduction in the current drawn, or torque developed, by the motor on full-voltage is desirable.

The current drawn from the line is reduced in proportion to the square of the voltage tap used. For example, if the motor is connected to the 80% voltage tap, the current drawn from the line will be approximately 64% of the full-voltage starting current of the motor. Since the torque developed by an induction motor also varies as the square of the voltage impressed on its terminals, the ratio of starting torque to starting current (*torque efficiency*) remains essentially the same as with full-voltage starting.

**Manual Reduced-voltage Resistor Type Controllers** are available in ratings up to 15 Hp. at 220 volts, and 20 Hp. at 440 and 550 volts. They consist of a rotating drum switch and a resistor. Rotation of the former connects the motor to the line through the entire resistor, and then successively short-circuits sections of the resistor until the motor is connected directly to the line. Neither overload nor under-voltage protection are provided. These controllers are used largely for motors driving machine tools, hoists, small cranes and similar applications where manual control of the torque delivered by the motor is required.

**Magnetic, Reduced-voltage Auto-transformer Controllers** are available in all sizes. These controllers are similar to the manual auto-transformer type, except that in place of the manual switch, magnetic contactors and a relay, usually of the definite time type, are provided to effect the transfer from reduced voltage to full voltage. Overload and under-voltage protection are provided. The latter may be obtained by the use of a time-delay push-button station, or, in the case of contactors held in by a mechanical latch, a time delay under-voltage tripping mechanism may be provided on the contactor itself. General-purpose and dust-tight enclosing cases are available. Completely oil-immersed controllers, both low voltage and high voltage, are available for use in corrosive atmospheres.

**Magnetic Reduced-voltage Resistor Type Controllers** are available in all sizes. They are similar to the auto-transformer type except that a resistor, inserted in series with the motor windings at start, is used, instead of an auto-transformer, to obtain the reduction in voltage. Since the resistor is simply short-circuited as the motor comes up to speed, the circuit to the motor is not opened during the starting period. Hence this type of controller is well adapted for use where the starting current limitations are of the type which do not limit the total current which may be drawn, provided the current is built up in steps of a certain magnitude without opening the circuit between steps. Frequently, a number of accelerating contactors and relays are provided. These short-circuit the starting resistor in steps, in order to limit the current increment on each step to the required value.

Unlike auto-transformer starting, resistor starting results in a reduction in the starting torque efficiency, since the current drawn from the line is reduced in proportion to the voltage impressed on the motor, while the starting torque is reduced in proportion to the square of the voltage.

**Multi-speed Controllers.**—Controllers for multi-speed induction motors are available in both the manual and magnetic type. The former consist of a rotating drum switch, and can be obtained in sizes up to 5 Hp. at 220 volts, and $7^1/_2$ Hp. at 440 and 550 volts for two-, three-, or four-speed motors. They do not provide overload or under-voltage protection. The magnetic type is available in all sizes. They are made up of magnetic contactors, one for each speed, suitably interlocked so only one can be closed at a time. An overload relay for each speed is required to give complete overload protection. With a momentary-contact push-button station (one start button for each speed) under-voltage protection is provided. Controllers for two-speed motors can be provided with a *compelling relay*, which makes it necessary that the motor be started on the low speed only, or with a *sequence relay* which starts the motor on low speed regardless of which start button is pressed, but automatically transfers to the high speed after a definite time delay when the high-speed button is pressed. General-purpose enclosing cases normally are supplied.

A multi-speed motor also may be controlled by a manually-operated switch, which serves to make the proper connections for each speed, plus a line switch, manual or magnetic, for making and breaking the circuit to the motor. Since the former is operated only when the line switch is open, it does not have to open or close on current, and a knife-switch or inexpensive type of drum switch can be employed. Under-voltage protection may be provided in the line switch. In place of the line switch, a reduced voltage controller may be employed to reduce the starting current.

**Reversing Controllers** may be of the manual or magnetic type. The former consist of drum switches, and are available in sizes up to 10 Hp. at 220 volts, and 15 Hp. at 440 or 550 volts. They do not provide overload or under-voltage protection. The magnetic type is made up of two magnetic contactors and is available in all sizes. The contactors usually are interlocked mechanically, so that both cannot be closed at the same time. Overload and under-voltage protection normally are provided. A 3-button push-button station is required. General-purpose, water-tight, and dust-tight enclosing cases are available. Reversing control also may be provided by a manually-operated knife switch which serves to reverse the connections to the motor plus a manual or magnetic, full-voltage or reduced-voltage controller for making and breaking the circuit to the motor.

## Wound-rotor Motors

Wound-rotor induction motors require control for both the primary (stator) winding and the secondary (rotor) winding.

**The Primary Control** serves to connect the primary winding to the source of power. It is similar to squirrel-cage motor control of the full voltage type, and may be either manual or magnetic.

**The Secondary Control** serves to vary the resistance of the secondary circuit of the motor, *i.e.*, to provide a high resistance at the start, and to decrease it as the motor comes up to speed. It consists of a resistor which is connected across the slip rings of the motor and manual or magnetic switches for short-circuiting the resistor in steps as the motor comes up to speed. The resistor usually is designed to limit, to the full-load values, the current drawn and the torque developed by the motor. As the resistor is short-circuited the starting torque increases, up to the maximum torque of the motor, with a corresponding increase in current. If a portion of the resistor is allowed to remain in the circuit, the motor will operate at reduced speed. In this case the resistor must be designed for continuous duty. Before closing the primary switch, the full value of secondary resistance should be inserted in the circuit.

**Manual Primary and Secondary Control** may consist of a single drum switch with contacts for closing the primary circuit, as well as for short-circuiting the secondary resistor. A separate resistor must be provided. These drum switches are available in sizes up to 100 Hp. at 220 volts, and 200 Hp. at 440 or 550 volts. They frequently are arranged to reverse the motor as well by changing the primary connections. Manual primary and secondary control, in all sizes, may be provided by a face-plate type rheostat, or drum switch, with resistor for secondary control, combined with a manual full-voltage controller for primary control. In case an oil-circuit breaker is used for the latter it generally can be provided with a *magnetic lock*, which prevents the breaker from being closed unless the secondary controller is in the starting position, *i.e.*, all the resistance is in the circuit.

**Magnetic Primary and Manual Secondary Control** is similar to the type just described except that a magnetic controller is used for primary control. The secondary controller usually is so arranged that moving the operating handle to the first position closes the control circuit to the primary switch, causing it to close. Thus complete control of the motor is obtained at the secondary controller.

**Magnetic Primary and Secondary Control** employs magnetic contactors for the primary switch and also for short-circuiting the secondary resistor. Definite time relays, or current relays which operate in response to the drop in secondary current as the motor comes up to speed, are used to close the several secondary contactors in proper sequence. Overload and under-voltage protection normally are provided. The controllers may be obtained in the open type, or with general-purpose enclosures. Although more costly than other types, these controllers give complete control from a remotely mounted push-button. They also can be obtained with an extra contactor for automatic reversing.

**COSTS.—Squirrel-cage Induction Motors.**—Controllers for polyphase induction motors, in 1936, ranged approximately as follows:

**Full-voltage, Magnetic Type, 220 volts,** $13 for 2-Hp. controllers, $52 for 25-Hp. and 30-Hp., $232 for 60-Hp. to 100-Hp., $673 for 125-Hp. to 200-Hp. controllers; **440 volts,** $13 for 2-Hp., $52 for 30-Hp. and 50-Hp., $232 for 150-Hp., and 200-Hp., $673 for 250-Hp. to 400-Hp., $799 for 500-Hp. and 600-Hp.; **2200 volts,** $395 for 50-Hp. to 200-Hp., $500 for 250-Hp. to 700-Hp.

**Reduced-voltage, Auto-transformer Magnetic Type, 220 volts,** $155 for 5-Hp. to 15-Hp. controllers, $384 for 40-Hp. and 50-Hp., $604 for 100-Hp., $1137 for 150-Hp., $1405 for 250-Hp.; **440 volts,** $155 for 15-Hp. controllers, $390 for 60-Hp. and 100-Hp., $567 for 150-Hp., $1155 for 250-Hp.; $1416 for 400-Hp., $1633 for 500-Hp.; **2200 volts,** $739 for 50-Hp. controller, $758 for 100-Hp., $782 for 150-Hp., $795 for 200-Hp., $1353 for 300-Hp., $1423 for 500-Hp., $1575 for 800-Hp.

Costs of magnetic type controllers include a separately-mounted start-stop push-button station.

**Reduced-voltage Auto-transformer Manual Type, 220 volts,** $91 for 5-Hp. to 15-Hp. controllers, $173 for 50-Hp., $253 for 100-Hp., $694 for 150-Hp.; **440 volts,** $91 for 15-Hp., $104 for 50-Hp., $186 for 100-Hp., $202 for 150-Hp., $277 for 200-Hp., $695 for 300-Hp.; **2200 volts,** $383 for 50-Hp., $404 for 100-Hp., $428 for 200-Hp., $454 for 300-Hp., $970 for 500-Hp., $1257 for 800-Hp.

**Wound-rotor Induction Motors.**—The costs for full voltage controllers for squirrel-cage motors, given above, apply also to primary control for wound-rotor induction motors. Approximate 1936 costs of manual secondary controllers for wound-rotor induction motors were as follows: For starting duty, $96 for 5-Hp. to 10-Hp., $129 for 25-Hp., $144 for 50-Hp., $163 for 100-Hp., $262 for 200-Hp., $322 for 300-Hp., $531 for 500-Hp.; for speed regulating duty, $103 for 5-Hp., $133 for 15-Hp., $184 for 25-Hp., $236 for 50-Hp., $366 for 100-Hp., $545 for 150-Hp., $676 for 200-Hp.

## 4. CONTROL FOR DIRECT-CURRENT MOTORS

**TYPES.**—Direct-current motor controllers of the following types are in general use: *a*. Manual controllers: 1. Full-voltage, constant speed; 2. Reduced-voltage, constant speed; 3. Reduced-voltage, adjustable speed, by field control; 4. Reduced-voltage, adjustable speed, by armature control; 5. Reduced voltage, adjustable speed, by armature and field control; 6. Drum controllers. *b*. Magnetic controllers: 1. Full-voltage, constant speed; 2. Reduced-voltage, constant speed; 3. Reduced-voltage, adjustable speed, by field control.

**Manual Full-voltage Controllers** are available in ratings up to 1 Hp. at 115 and 230 volts. They consist of a single-pole or double-pole switch and a single-element thermal type overload relay, mounted in a general-purpose or explosion-proof (Class I, Group D, conditions) enclosing case. These simple and low cost controllers are applicable to small motors where full-voltage starting and manual control are acceptable.

**Manual Reduced-voltage, Constant-speed Controllers** are available in ratings up to 100 Hp. at 115 volts, 200 Hp. at 230 volts, and 400 Hp. at 550 volts. They consist essentially of a dial-type switch and a resistor. As the operating handle is turned, the switch first connects the motor armature to the line through the entire resistor, and then short-circuits the resistor in steps until the motor is on full voltage. Full voltage is applied to the field winding throughout. A retaining magnet, which holds the operating arm in the running position, releases the arm and disconnects the motor on failure of voltage. Controllers rated 550 volts usually have a magnetic contactor connected in series with the circuit to the motor. This interrupts the current when the motor is shut down, and avoids the breaking of current on the starting switch contacts. Controllers of the higher horsepower ratings generally are available with a magnetic line contactor for breaking the circuit, and a manually-operated air circuit breaker with an automatic overcurrent trip to provide overload protection. Controllers of the open type and with general-purpose enclosing cases are available.

**ADJUSTABLE SPEED CONTROLLERS. Field Control Speed Adjustment.**—Controllers are available in ratings up to 100 Hp. at 115 volts, 200 Hp. at 230 volts, and 400 Hp. at 550 volts. They are similar to the constant speed controllers described above, with the addition of a resistor, inserted in series with the field winding, and means for short-circuiting the resistor in steps, thereby varying the field current and the speed of the motor. In the smaller sizes, the dial switch has an auxiliary arm and an extra set of segments or buttons by means of which the field current is varied. In the larger sizes, a separate field rheostat is provided. The control is so arranged that all of the resistance in the field circuit must be short-circuited before the motor can be started.

**Armature Control Speed Adjustment.**—Controllers are available in ratings up to 50 Hp. at 115 volts, 60 Hp. at 230 volts, and 5 Hp. at 550 volts. They are similar to the constant speed controllers, except that they have a continuously rated armature resistor, and the operating handle of the dial switch can be left in various positions to leave a certain portion of the resistor in the circuit. Thus the voltage impressed on the armature of the motor can be varied, with consequent variation in speed. Speed reduction down to 50% of full speed is standard. With this type of control the speed of the motor varies considerably with the load. It cannot be used where close speed regulation is required

**Armature and Field Control Speed Adjustment.**—Controllers are available in ratings up to 10 Hp. at 115 volts, 20 Hp. at 230 volts, and 5 Hp. at 550 volts. They consist of a combination of the two types described above. A variable armature resistance, sufficient to give 50% speed reduction, and a variable field resistance to give 25% speed increase, are standard.

**Manual Drum Controllers** of the full-voltage type are available in ratings up to 5 Hp. at 115 and 230 volts. The reduced-voltage type can be obtained in ratings up to 40 Hp. at 115 volts, 75 Hp. at 230 volts, and 100 Hp. at 550 volts. Both types can be obtained for reversing as well as for non-reversing duty. The reduced-voltage type also can be obtained suitable for adjustable speed operation either by field or by armature control. Where field control is provided, the field resistor usually is mounted on the side of the controller, and the drum switch has segments for short circuiting the resistor in steps as the operating handle is turned. The armature resistor usually is mounted separately.

Drum controllers arranged to provide *dynamic braking* also can be obtained. The motor is connected as a generator and a resistor is connected across the armature so that when driven by an overhauling load, power is delivered to the resistor which holds back the load.

Since drum controllers do not provide overload or under-voltage protection, a *protective panel*, consisting of a magnetic contactor and a temperature overload relay mounted in an enclosing case, often is used. The contactor will open on failure of voltage, disconnecting the motor, after which the drum controller must be returned to the off position to reclose the contactor. In the event of injurious overload, the relay will open the contactor. An open-close push-button station is recommended. This may be located at any convenient place, and provides an additional means for stopping the motor. Drum controllers are used with motors driving machine tools, cranes, hoists and similar applications, where a convenient and compact manual controller is required.

**Magnetic Full-voltage Controllers** are available in ratings up to 1/2 Hp. at 115 volts and 3/4 Hp. at 230 volts. They consist of a magnetic contactor mounted in a general-purpose enclosing case. A start-stop push-button station or similar device is required for starting and stopping the motor.

**Magnetic, Reduced-voltage, Constant-speed Controllers** are available in all ratings. They consist of a starting resistor, two or more magnetic contactors, and relays, usually of the definite time type, for closing the contactors in proper sequence to short-circuit the resistor as the motor comes up to speed. In some types, accelerating contactors, incorporating a time-delay feature, are used. These eliminate the necessity for a separate relay. A single-element temperature-overload relay and a general-purpose enclosing case usually are provided. Controllers arranged for dynamic braking with or without reversing features also are available.

**Magnetic, Reduced-voltage, Adjustable-speed Controllers,** with speed adjustment by *field control* are available in all sizes. They are similar to the type above described, with the addition of a field rheostat for varying the field current, and hence the speed, of the motor. A *field accelerating relay* often is added, which prevents high armature current when the motor accelerates rapidly from basic speed (full-field) to a higher speed (weak field). A "field protective" relay may be installed to protect the motor from excessive speed if the field circuit is opened accidentally.

**COSTS** of the more generally used controllers for D.C. motors ranged, in 1936, approximately as follows:

**Manual Controllers, Constant-speed, 115 volts,** $12 for 1-Hp. controllers, $18 for 3-Hp., $22 for 5-Hp., $37 for 7 1/2-Hp., $46 for 10-Hp., $65 for 20-Hp., $85 for 30-Hp., $249 for 50-Hp., $422 for 100-Hp.; **230 volts**, $12 for 1-Hp., $18 for 3-Hp., $22 for 5-Hp., $23 for 7 1/2-Hp., $41 for 10-Hp., $48 for 20-Hp., $65 for 30-Hp., $90 for 50-Hp., $256 for 100-Hp., $266 for 150-Hp., $422 for 200-Hp.; **550 volts,** $22 for 1-Hp. and 3-Hp., $23 for 5-Hp., $28 for 7 1/2-Hp., $72 for 10-Hp., $80 for 20-Hp., $158 for 30-Hp., $164 for 50-Hp., $200 for 100-Hp., $214 for 150-Hp., $323 for 200-Hp., $358 for 300-Hp., $469 for 400-Hp.

**Manual Adjustable-speed Controllers, Field Control.—115 volts,** $36 for 1-Hp., $38 for 3-Hp. and 5-Hp., $46 for 7 1/2-Hp., $77 for 10-Hp., $120 for 20-Hp., $129 for 30-Hp.,

$405 for 50-Hp., $587 for 100-Hp.; **230 volts**, $36 for 1-Hp., $38 for 3-Hp. and 5-Hp., $46 for 7 $^1/_2$-Hp., $77 for 10-Hp and 20-Hp., $120 for 30-Hp., $136 for 50-Hp., $416 for 100-Hp., $428 for 150-Hp., $587 for 200-Hp.; **550 volts**, $317 for 30-Hp. and 50-Hp., $364 for 10-Hp., $405 for 150-Hp., $440 for 300-Hp., $645 for 400-Hp.

**Manual Adjustable-speed Controllers, Armature Control.—115 volts,** $29 for 1-Hp., $47 for 3-Hp., $81 for 5-Hp., $96 for 7 $^1/_2$-Hp., $99 for 10-Hp., $214 for 20-Hp., $319 for 30-Hp., $473 for 50-Hp.; **230 volts,** $29 for 1-Hp., $47 for 3-Hp., $75 for 5-Hp., $81 for 7 $^1/_2$-Hp., $86 for 10-Hp., $144 for 20-Hp., $280 for 30-Hp., $373 for 50-Hp.

**Magnetic Constant-speed Controllers.—115 volts,** $41 for 1-Hp. and 3-Hp., $64 for 5-Hp. and 7 $^1/_2$ Hp., $70 for 10-Hp., $229 for 20-Hp., $364 for 30-Hp., $517 for 50-Hp., $529 for 75-Hp.; **230 volts,** $41 for 1-Hp. and 3-Hp., $47 for 5-Hp. and 7 $^1/_2$-Hp., $64 for 10-Hp., $70 for 20-Hp., $211 for 30-Hp., $375 for 50-Hp., $517 for 100-Hp., $529 for 150-Hp.; **550 volts,** $70 for 1-Hp. and 3-Hp., $76 for 5-Hp. and 7 $^1/_2$-Hp., $105 for 10-Hp., $111 for 20-Hp., $211 for 30-Hp., $252 for 50-Hp., $375 for 100-Hp., $387 for 150-Hp.

**Magnetic Adjustable-speed Controllers, Field Control.—115 volts,** $64 for 1-Hp. and 3-Hp., $88 for 5-Hp. and 7 $^1/_2$-Hp., $94 for 10-Hp., $317 for 20-Hp., $440 for 30-Hp., $739 for 50-Hp., $751 for 75-Hp.; **230 volts,** $64 for 1-Hp. and 3-Hp., $70 for 5-Hp. and 7 $^1/_2$-Hp., $88 for 10-Hp., $94 for 20-Hp., $305 for 30-Hp., $451 for 50-Hp., $745 for 100-Hp., $757 for 150-Hp.; **550 volts,** $99 for 1-Hp. and 3-Hp., $117 for 5-Hp. and 7 $^1/_2$-Hp., $123 for 10-Hp., $129 for 20-Hp., $305 for 30-Hp., $340 for 50-Hp., $451 for 100-Hp., $463 for 150-Hp.

Costs of magnetic controllers include a start-stop push-button station for separate mounting.

## 5. CONTROL FOR SYNCHRONOUS MOTORS

The control for the armature (primary) winding of a synchronous motor is similar to that provided for a squirrel-cage induction motor. See p. 25–54. It may be of the full-voltage or reduced-voltage type, either manual or magnetic. In addition, control for the field winding must be provided. This control usually is of the magnetic type, so that after the primary control has connected the armature winding to the A.C. power lines, direct current automatically is applied to the field winding when the motor has accelerated to the proper speed, *i.e.*, 95 to 98% of synchronous speed. When the magnetic field control is combined with magnetic primary control, the complete controller is designated *magnetic* and when combined with manual primary control it is designated *semi-magnetic.*

A field contactor and *field application relay* are required to apply field excitation automatically. The latter may be of the definite time type, or it may be a slip-frequency relay. Such a relay operates on the change in frequency of the alternating current induced in the field winding as the motor accelerates. In addition, a *discharge resistor* must be connected across the field winding during the starting period in order to limit the voltage induced in that winding. The discharge resistor circuit is opened when field excitation is applied, either by normally closed contacts on the field contactor or by a separate field discharge contactor actuated by the field application relay. Synchronous motor controllers also include a *field removal relay* which operates automatically to open the field contactor and remove excitation, whenever the motor pulls out of synchronism. The latter condition may occur as a result of a high overload or a drop in line voltage. By removing field excitation, after the load or voltage returns to normal, the motor may be able to re-accelerate, and the field application relay will re-apply field so that normal operation is resumed automatically. If field excitation is not removed on pull-out the motor is apt to stall, and, in addition, is subjected to violent torque and current surges. Where the driven machine must be unloaded when starting, in order that the motor will accelerate and synchronize, it often is possible to provide an automatic, electrically-operated unloader, which can be connected to the field contactor. Then on pull-out, the automatic removal of field also will unload the machine, so that the motor can re-synchronize, after which load automatically is re-applied. The field removal relay may operate on the abrupt drop in the power-factor of the current drawn by the motor as it pulls out of step, or on the increase in line current under this condition, or on the current induced in the field winding as the motor speed drops below synchronous speed.

**Means for Adjusting D.C. Excitation** applied to a synchronous motor also should be provided. Where an exciter is used to supply excitation to a single synchronous motor, adequate control of the excitation can be obtained by means of the exciter field rheostat. However, if a single D.C. generator supplies excitation to two or more synchronous motors, a field rheostat must be connected in series with the field winding of each motor. Synchronous motor controllers usually are arranged for mounting either an exciter field rheostat, a motor field rheostat, or both.

Usual practice provides synchronous motor controllers with two ammeters, an A.C. ammeter for reading line current, and a D.C. ammeter for reading field current. Additional instruments, such as an A.C. voltmeter, indicating wattmeter, or watt-hour meter, are often valuable additions.

Like induction motor controllers, synchronous motor controllers normally are provided with a thermal type *overload relay*. Time-delay *under-voltage protection* is standard for controllers rated 2200 volts and above, while for controllers of lower voltage rating, instantaneous under-voltage protection is standard, but the time-delay type can be obtained. Standard controllers are of the open type, but general-purpose enclosing cases are available.

**TYPES.**—Synchronous motor controllers of the following types are commonly used: *a*. Magnetic, full-voltage; *b*. Semi-magnetic, full-voltage; *c*. Magnetic, reduced-voltage, auto-transformer type; *d*. Semi-magnetic, reduced-voltage, auto-transformer type; *e*, Magnetic, reduced-voltage, resistor type; *f*. Magnetic part-winding.

Types *a*, *c*, and *e* are similar to the corresponding types of magnetic squirrel-cage induction motor controllers, with the addition of the automatic field control and ammeters described above. Types *b* and *d* are similar to the corresponding type of manual squirrel-cage induction motor controllers with the same additional features.

**Magnetic Part-winding Controllers** are arranged to start a motor by energizing only a portion of the complete armature winding and then, after the motor has accelerated, energizing the remainder of the winding in one or more steps. The motor must be designed especially for this type of starting, with a *multiple circuit* armature winding and sufficient terminal leads provided to allow energization of the various circuits independently. The effect of this starting method is to reduce the current drawn from the line and the torque developed by the motor at start, to give the effect of reduced-voltage starting without the use of an auto-transformer, resistor, or other voltage reducing device. The amount of reduction in torque and current depends on the percentage of the winding energized, and also on the characteristics of the individual motor. With some motors the torque is reduced in proportion to the reduction in current, while in others a considerably greater reduction in torque occurs. Like reduced-voltage resistor starting, part-winding starting has the advantage that the circuit to the motor is not opened during the starting period, making the method particularly applicable where the starting current limitations are of the increment type. Motors of relatively high voltage in relation to their horsepower cannot be economically designed for part-winding starting. The method is most applicable to low-speed machines of large horsepower and moderate voltage. Most motors and controllers for part-winding starting are arranged to give just one reduced kva. step (two-point starting), but in many cases they can be provided with two, three, or more reduced kva. steps.

**COSTS** of controllers, open type, for synchronous motors, in 1936, ranged approximately as follows:

**Full-voltage Magnetic Type, Unity Power Factor: 220 volts,** $393 for 50-Hp. and 60-Hp. controllers, $514 for 100-Hp. and 125-Hp., $647 for 150-Hp., $750 for 200-Hp.; **440 volts,** $303 for 50-Hp. and 60-Hp. controller, $393 for 100-Hp., $430 for 150-Hp., $514 for 200- and 250-Hp., $647 for 300-Hp., $750 for 400-Hp. and 500 Hp.; **2200 volts,** $647 for 50-Hp. to 350-Hp. controllers, $750 for 400-Hp. to 500-Hp.

**Reduced-voltage, Auto-transformer, Magnetic Type, Unity Power Factor: 220 volts,** $708 for 50-Hp., $998 for 100-Hp., $1513 for 150-Hp., $1694 for 200-Hp.; **440 volts,** $563 for 50-Hp., $702 for 100-Hp., $871 for 150-Hp., $1035 for 200-Hp., $1548 for 300-Hp., $1755 for 400-Hp. to 500-Hp.; **2200 volts,** $1089 for 50-Hp. controller, $1101 for 60-Hp. to 100-Hp., $1131 for 150-Hp., $1143 for 200-Hp., $1258 for 300-Hp., $1621 for 400-Hp. to 500-Hp.

The costs of magnetic type controllers include a start-stop push-button station for separate mounting.

**Full-voltage Semi-magnetic Type, Unity Power Factor: 440 volts,** $532 for 225-Hp. to 350-Hp.; **2200 volts,** $730 for 50-Hp. to 250-Hp., $742 for 300-Hp. to 500-Hp.

**Reduced-voltage, Auto-transformers, Semi-magnetic Type, Unity Power Factor: 220 volts,** $424 for 50- and 60-Hp., $490 for 100-Hp., $1071 for 150-Hp., $1131 for 175-Hp.; **440 volts,** $351 for 50-Hp., $430 for 100-Hp., $448 for 150-Hp., $502 for 200-Hp., $1131 for 300-Hp.; **2200 volts,** $659 for 50-Hp. and 60-Hp., $678 for 100-Hp., $690 for 150-Hp. to 200-Hp., $702 for 250-Hp. to 350-Hp., $1186 for 400-Hp., $1204 for 500-Hp.

## DUST COLLECTION *

By M. S. Kice, Jr.

### 1. CHARACTERISTICS OF DUST

There is no standard definition of industrial dust. Generally it comprises powdered minerals, fine metals, organic dust, chips and shavings. In the following discussion, all of the more or less finely divided particles will be treated as dust.

**COMMON TYPES OF DUST.**—1. Wood sawdust and shavings from planing mill equipment. 2. Metallic and abrasive grindings and lint from metal grinding and polishing machinery. 3. Stone-working dust. 4. Foundry dust. 5. Various types of ore dust at varying temperatures. 6. All pulverized materials such as dried and powdered milk, cement, talcum powder, pulverized coal, etc. 7. Cinder from stoker-fired boilers. 8. Fly ash from pulverized fuel boilers.

**NATURE OF DUST.**—Combinations of various properties of dust are factors affecting the choice of the type of suitable dust collector, as well as its collecting efficiency. The recognized method of proving collector efficiency is the testing of actual samples of a specific dust. Combinations of the many variables involved in dust collecting work would lead to speculative results if the subject were treated mathematically.

**Shape.**—Dust particles formed at high temperature often are hollow or globular. Mineral particles from substances at ordinary temperature usually are solid. Most organic dusts are fuzzy. Rarely is the shape uniform.

**Fineness.**—Metallic and wood particles are coarse. Organic powders, such as flour, are extremely fine. Mineral dusts in industrial use are graded through standard mesh screens. Finer dusts are measured by calibrated microscopic photography and by flotation. The finest mesh screen available has 400 meshes to the inch. The square power of a mesh number represents the number of mesh openings per square inch. Thus, a 400-mesh screen has 160,000 openings per square inch. Each net opening is $2.03 \times 10^{-6}$ sq. in. The wires forming this mesh are $1.075 \times 10^{-3}$ in. diameter. For comparison, the diameter of a No. 40 B. & S. bare wire is $3.441 \times 10^{-3}$ in. Fine dust is measured in microns, which is a linear measure equal to $3.93 \times 10^{-5}$ in.; 1300 particles one micron diameter can be assembled in one plane of one mesh opening of a 400-mesh screen. Table 1 illustrates proportions of common screens.

**Table 1.—Properties of Common Screens**

| Screen mesh | 20 | 40 | 60 | 80 | 100 | 150 | 200 | 325 | 400 |
|---|---|---|---|---|---|---|---|---|---|
| Width of mesh opening, in. | 0.0340 | .0150 | .0087 | .0068 | .0058 | .0041 | .0029 | .0017 | .001425 |
| Approx. microns across net opening | 850 | 375 | 217 | 170 | 147 | 102 | 74 | 43 | 36 |
| Proportional opening, in.* | 240 | 105 | 61 | 48 | 41 | 29 | 20 | 12 | 10 |

* These values represent an equivalent approximate size sphere to the same scale as represented by one micron being enlarged to the size of a circle inscribed in the hexagon of an engineer's common lead pencil, namely, 0.28 in. These values are given to allow visualization of these proportions.

**Uniformness.**—Rarely is dust uniform. Its fineness has to be described in percentage values of that dust that will pass through successive mesh screens. As an illustration of uniformness grading, the following represents the mesh analysis of common Portland cement.

| Mesh | 40 | 60 | 100 | 150 | 200 | 325 |
|---|---|---|---|---|---|---|
| Percentage passing through | 99.9 | 99.8 | 98.5 | 95.0 | 83.0 | 61.0 |

For making this screen test, circular frames about 1 1/2 in. high and 8 in. diam., con-

---

*Acknowledgments.—E. J. Tangerman, Managing Editor, *Power*. H. O. Danz, Manager Dust Collector Division, American Blower Corporation. W. O. Vedder, Pangborn Corporation.

taining a stack of screens in the above order and mounted in a vibrating machine are used. A weighed sample is placed on the top screen. After screening, the material on each screen and that which passed through the last screen is weighed. From these values the percentage through each mesh is calculated.

**Specific Gravity** is that of the dust, not of the solid from which the dust is produced.

**Concentration** relates to grains per cubic foot of air. It is a measure of the amount of material possible to extract from a given quantity of air.

**Toxicity.**—In addition to being careful to remove poisonous dusts from an atmosphere, care must be taken to protect those testing such dust samples, and those handling the material collected in the field.

**Adhesiveness.**—Sticky dusts cannot be caught in dust collectors of any type unless provision is made for periodic cleaning and scraping.

**Explosiveness.**—Fine inflammable dusts are extremely hazardous. The air stream must be kept below the flash temperature of the mixture, and provision assured to guard against spark or other ignition. All metallic parts must be grounded. The rotating parts of fans handling such dust should be made of spark-proof material.

**Electrostatic Charge.**—Charges of static electricity that tend to agglomerate dust particles allow a greater collection efficiency of the fine particles because of their adherence to the larger particles.

**GROUPS OF DUST.**—1. Dust hazardous to health, agriculture and machinery. 2. General nuisance dusts, as fly ash. 3. Dusts useful as by-products, products and fuels, as asphalt topping, plaster of Paris and pulverized coal. 4. Valuable dusts, as gold grindings, etc.

## 2. TYPES OF DUST COLLECTORS

**SETTLING CHAMBERS** are the oldest form of dust separators. A large dead air space receives dust-laden air and contains it long enough for the dust to settle. A modified form consists of a pocket trap in an ordinary duct to drop out heavy particles accidentally or purposely admitted to the air stream.

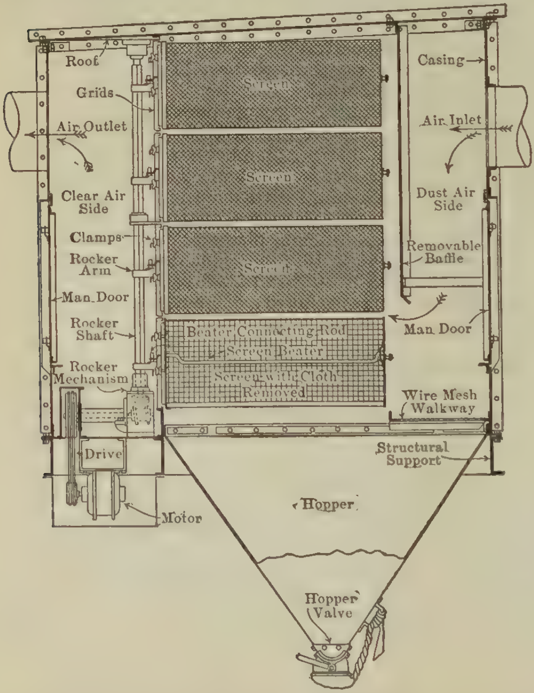

Fig. 1. Section of Cloth Screen Filter

**FILTERS** are a type of collector that appear in various forms. The modern adaption consists of a viscous covered channel, forming tortuous paths for dust-laden air. The dust impinges on the viscous surface. When fully loaded some types are cleaned in an oil bath. Other types are discarded and replaced with new filter elements.

**Bag-type Air Filters** consist of cotton or woolen socks or bags arranged in battery, suspended vertically from rings at the top and secured at the bottom around thimbles which protrude from the floor. Gases enter from a lower plenum. The bags expand as they are under pressure. The bag house is divided into several compartments, to permit one compartment to be isolated from the system and cleaned. This is accomplished by a mechanical shaking system which dislodges the arrested material on the interior of the bag, which material falls to the plenum chamber below and is extracted. A velocity of about 2.5 ft. per min. is figured through the bag surface. Resistance to air flow varies about as the 1.7th power in terms of air velocity, and increases considerably as the bag material becomes loaded with dust. This resistance at constant velocity varies from about 0.5 in. to 3 in. static water gage. Commercially, bag-type filters are used for fumes and gases from smelter furnaces of various kinds for separation of finely divided ores and metals. The gases are cooled to about 180° F.

**Cloth Screen Filter.**—A modern modification of the bag-type filter consists of flat cloth fabric screens applied over a series of rectangular frames and enclosed in a sheet-metal box framework. The cloth covers both sides and three edges of the frame. The fourth edge, left open, forms the flue for the clean air outlet. Hoppers are provided below to catch the dust. The cloth screen frames are connected to a rapping device to dislodge dust packed on the cloth. Coarser dust is settled out prior to encountering the screens, and in some designs a settling chamber is provided ahead of the collector. Fig. 1 shows a typical cross-section of a cloth screen filter.

**Intermittent Type Filters** allow the cloth to be cleaned by periodic shaking, the exhaust fan being shut down. The cleaning frequency is determined by specific conditions. It averages 5 to 10 min. in each 4 to 5 hr. operation. The advantage of the intermittent type is lower first cost. It is suitable where dust concentration is not severe, or where the cleanout time is not disadvantageous.

**Continuous Type Filters** are used for heavy dust concentration or where shut-down periods are prohibitive. They consist of two intermittent types, cross-connected to allow one collector for service operation, while the other is being cleaned. The switch-over can be arranged for manual operation with cross-connecting dampers, or the entire period can be controlled automatically.

**ELECTROSTATIC PRECIPITATORS.**—High voltage direct current fed to electrodes in series gives the suspended dust particles a negative charge, causing them to be attracted by the positively charged electrodes to which the dust adheres. When the current is interrupted and the plates rapped, the dust is precipitated to the hoppers below. Lighter dusts are removed by scraping. The composite plate precipitator has two or more separate banks of electrodes in series, each up to 15 parallel ducts formed by large concrete slabs which act as grounded collecting electrodes. Discharge electrodes hang centrally in the ducts. The curtain rod precipitator is similar, except that collecting electrodes are pipe frameworks into which are threaded many vertical parallel rods. These curtains, hung from the top, can be lifted and dropped against anvils at the bottom, thereby vibrating collected dust loose. Rapping is done continuously or at necessary intervals by a solenoid-actuated mechanism. The vertical pocket electrode precipitator allows gas to enter the hopper and rise through ducts to the breeching. Ducts are formed by parallel electrodes built up of six individual sections or hung from the top supporting member. Pockets in the sides of these boxes provide louvre-like openings which catch the dust when the section is vibrated, dropping it down through the center to the hopper out of the incoming gas path. Fig. 2 shows the composite plate type.

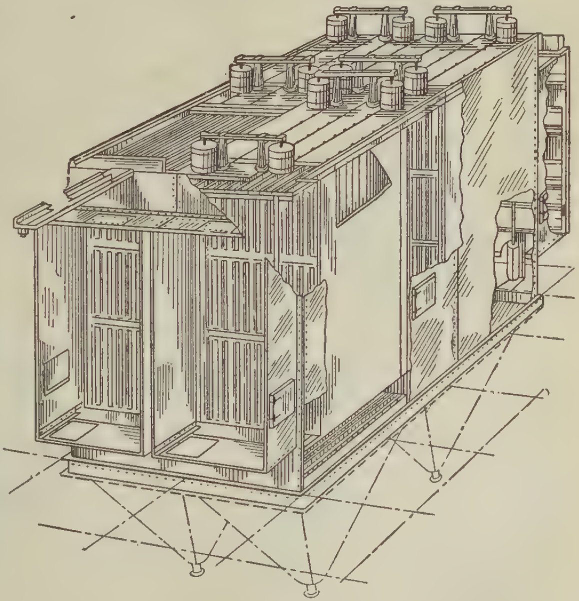

Fig. 2. Composite Plate Type Electrostatic Precipitator

**WET WASHERS.**—The simplest form of gas washer is the common air washer. See Kent's Mechanical Engineers' Handbook—Power, p. 11–52, forming Vol. 2 of this series.

It is efficient for light concentrations of dust soluble or wettable in water. For heavier dust concentrations, the lower tank is sloped and fresh water is used. Particles that will not wet do not puncture the water mist particle. Finely divided, the water surface tension prevents puncturing the water globule. Such dust passes through a common washer. Chemical treatment is possible to reduce the water surface tension. For cleaning products of combustion, the gas scrubber usually consists of plates, rods, links, etc., suspended in a gas stream and sprayed with water. Dust is washed down through the hopper. Sinuous paths through the scrubber increase cleaning efficiency. Materials not attacked by sulphurous and sulphuric acid must be used. The latter acid is formed by the combination of sulphur gases and the spray water.

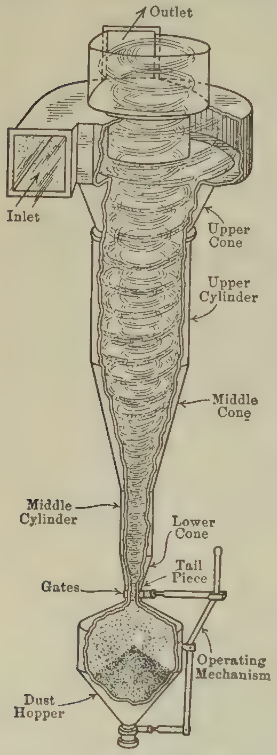

FIG. 3. Action of Vortex Collector and Receptacle

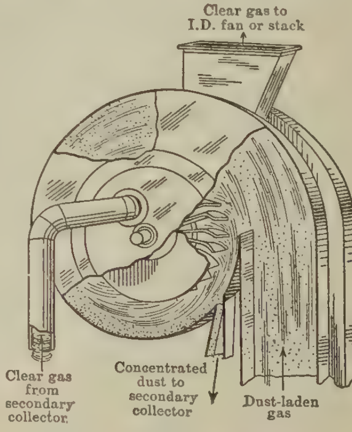
**CINDER TRAPS.**—Rows of diamond and other shaped sections, arranged staggered, are constructed with narrow slots on the side of the entering air. Heavier particles of dust, moving in a straight line, possess too much inertia to work around the staggered rows of baffles, and are trapped inside the hollow section and pass to a hopper below. The air sinuously moves around the staggered rows. Light dust particles move with the air stream.

**CENTRIFUGAL COLLECTORS.**—The same principle of nature that is used in cinder traps is utilized in a centrifugal collector. The dust-laden gas is rotated. The inertia of solid particles prevents them from accelerating toward the center. They strike the outer surface and either are skimmed off or drop down to a chamber below. The efficiency of the collector is directly proportional to the rotation of the air, which, in turn, is proportional to the pressure drop of the collector, and, again in turn, is proportional to the power put into the air stream.

**The Common Cyclone** collector usually consists of a conical lower half and an upper half, which either is likewise conical in the opposite direction or cylindrical. Dust-laden gas enters tangentially in the upper body. The air is rotated inside of the cyclone, and the cleaner air passes out at the top of the center of the whirl. This type is universally used for the collection of shavings, sawdust, etc., from woodworking establishments. Its pressure drop ranges from $^1/_2$ in. to 1 in. water gage.

**The Vortex Collector** is shown in Fig. 3. Dust-laden gas enters a scroll body, which rotates the air stream. Below, and extending downward, are a series of cones and cylinders. The decreasing cross-sectional radius spins the air stream into an extremely high velocity vortex. Dust particles impinge against the outer walls and work downward, passing out of the lower cylinder. A collar extends into the body of the vortex collector to skim off the clean air, which is discharged either through a vertical pipe or an outlet head; the latter is used when it is desired to carry the clean gas in the same plane as the entering gas. The dust outlets must be sealed, either by a rotary dust valve or a lower receptacle. Internal turbulence is eliminated, which prevents the fine particles re-entering the clean air stream. This type is used primarily in industrial process work of furnaces, roasters, calciners, crushers, grinders, etc., and in connection with spray dryers or towers for milk, soap or food products.



Clear gas to I.D. fan or stack
Clear gas from secondary collector
Concentrated dust to secondary collector
Dust-laden gas

FIG. 4. Spiral Scroll Collector

The pressure drop across the vortex collector depends on the air velocity and the size of the internal collar. The performance characteristics of this type afford unusually high collection efficiency for coarse and fine particles. The efficiency remains practically constant for a wide variation in dust concentration and air velocity.

**Spiral Scroll Collectors** ordinarily are used as a spiral inlet box on a single-inlet fan, or spiral inlet boxes on each side of a double-inlet fan. Fig. 4 shows a cross-section of this type. Dust-laden gases pass around the spiral, and the dust is forced to the outer wall. A scoop opening admits part of the gas to a cyclone collector for final separation. The clean gases pass back into the spiral scroll collector. The pressure drop across the spiral scroll collector operates the vortex collector without the use of additional fan equipment. The primary fan handles the full volume of the air. At the collector outlet, straightening vanes admit the cleaned air into the fan wheel. These vanes prevent internal turbulence in bleeding off clean air. The pressure drop is from 1 1/2 in. to 2 1/2 in. water gage.

**The Spiral Tube Precipitator** consists of a bank of parallel tubes. On the entering side of the dusty air, a streamline spiral rotates the air. The relatively small diameter of each rotating air stream eliminates the necessity for high-velocity rotation, as the dust particle has a long path to travel longitudinally and a short distance to travel axially. In the clean air end, a hollow tube protrudes into the outer tube to receive the clean center of the air stream, the dust passing through a circular orifice into a collecting chamber. From 5% to 10% of the primary air is bled off into a vortex collector for final separation, and the clean air is returned to the entrance of the spiral tube precipitator by means of a secondary fan. The collecting efficiency of this type of precipitator is extremely high for very fine particles. Its most popular application is the collecting of fly ash from boilers fired with pulverized fuel. Fig. 5 is a phantom cross-section of the spiral tube precipitator.

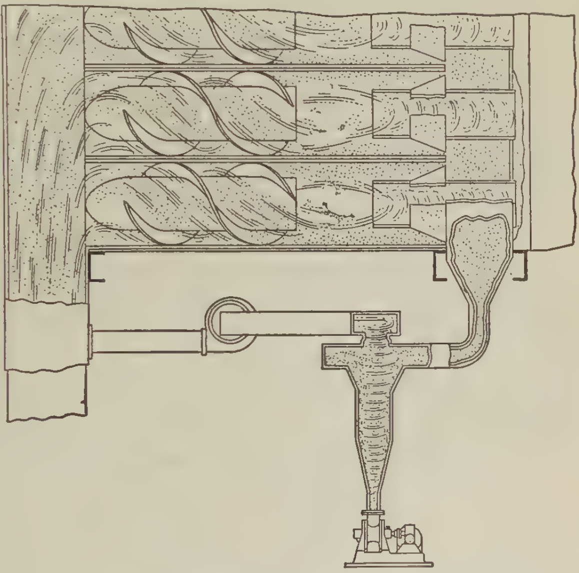


FIG. 5. Spiral Tube Precipitator Elements

## 3. DUST COLLECTING SYSTEMS

**FACTORS INFLUENCING REQUIREMENTS.**—1. Improvement of working conditions. 2. Nuisance elimination. 3. Value of recovered material. 4. Public liability. 5. State laws.

**FACTORS INFLUENCING CHOICE OF TYPE OF SYSTEM.**—1. Relative capital, power and maintenance costs. 2. Nature of dust involved. 3. Dust concentration. 4. Efficiency requirement of dust collection.

**TYPES OF SYSTEMS.**—The best known type of dust collector system is that involving vacuum hoods connected by branches to a main pipe, served by a fan which discharges to a collector.

**The Planing Mill Exhaust System** is an example of the branch pipe and vacuum hood system. Fig. 6 shows a typical arrangement, and Fig. 7 shows typical hoods. In addition to the branches for various hoods, a number of floor sweeps must be supplied and provided with shut-off gates. Ordinarily the size of main is established independently of the number of floor sweeps, as they are used intermittently. Table 2 shows size of hood connections for average woodworking machinery.

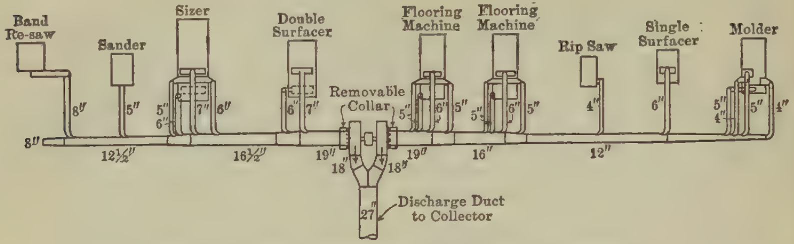

FIG. 6. Plan of Typical Planing Mill Exhaust System

**HOOD DESIGN.**—Requirements of good hood design are: 1. Minimum interference with machine operation. 2. Air to enter hood orifice nearly as possible in the same direction as particles are discharged from machine. 3. Close proximity of hood mouth to source of dust production source. 4. Removable sections in hood for clean-out, inspection and maintenance. 5. Desirable that machine builders incorporate hoods in the original design of the machine. 6. Sufficient entering air velocity into the hood to arrest and carry away generated dust particles.

**PIPING DESIGN.**—Points leading to good piping design are: Conveying-air velocity to be sufficiently high to carry entrained dust. 2. Piping to run in as direct a line as possible from hoods to collector or fan. 3. Non-interference with cranes, machinery and other necessary plant equipment. 4. Bottom of pipe should be on a straight line. The taper should be taken on the sides and top. 5. Branch angles preferably 30 deg. included angle between the branch and the main pipe. 6. Pipe joints lapped in direction of air flow, and soldered or welded. 7. Clean-outs to extend into the lower side of the duct and to be equipped with removable air-tight caps. 8. Floor sweeps provided where required. 9. Large-radius branch-pipe bends into the main pipe. 10. Blast gates to equalize suction. 11. Provision for future additional taps.

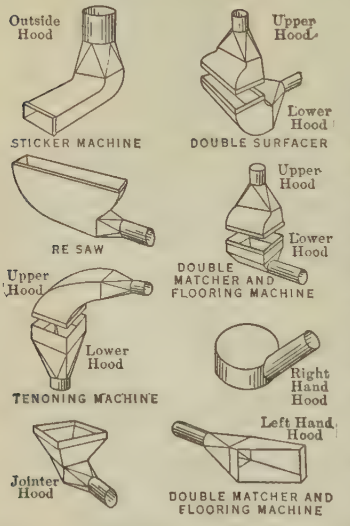

FIG. 7. Typical Hoods for Woodworking Machines

**COMPUTATION OF FAN DUTY.**—The cubic feet per minute (c.f.m.) moved by the exhaust fan is the product of the main duct area in square feet beyond the last branch to the main, and the air velocity in the duct at that point, in feet per minute. The static pressure is the sum of the duct resistance of the longest air path from the farthest machine to the inlet of the collector, plus collector loss, plus suction at the hood. See Kent's Mechanical Engineers' Handbook—Power, p. 1–81, forming Vol. 2 of this series, for duct resistance chart. This static pressure runs from 4 to 8 in. water gage, averaging about 5 1/2 in. The fan brake horsepower, read from the fan capacity table, should be increased 15–25% to allow for the extra weight of material in the air stream which the fan has to move. For data on fan capacity testing, see Kent's Mechanical Engineers' Handbook—Power, p. 1–55, forming Vol. 2 of this series.

**THE MAIN PIPE SIZE** is arrived at by several methods. One method is to add the area of the branches, increasing the main size to the fan outlet, which is 15% to 30% greater than the duct. Another common method is to add the areas of the adjoining pipes and increase the main beyond this junction by 10%; in other words, slowing the velocity down gradually toward the fan. In this case, the last main diameter is the diameter of the fan inlet. A third method consists of using a constant friction per 100 ft. of duct. For details of this method see chart, Kent's Mechanical Engineers' Hand-

**Table 2.—Sizes of Hood Connections for Woodworking Machinery**

| Type of Machine | Diameter of Pipe, in. | Type of Machine | Diameter of Pipe, in. |
|---|---|---|---|
| Matcher heads, each | 5 | Rip saws and resaws | |
| Sash and cabinet shaper, each head | 4 | Up to 14 in. diam | 4 |
| Door tenoner | 5 | 14 to 18 in. diam | 4 1/2 |
| Sash tenoner | 5 | 18 to 24 in. diam | 5 |
| Door and ash sticker, each head | 5 | Cut-off saws not over 16 in. diam | 4 |
| Blind slat sticker | 5 | Band saws | |
| Blind rail router | 4 | Up to 1 1/2 in. wide | 4 |
| Panel raiser, each head | 4 | 1 1/2 to 3 in. wide | 5 |
| Sand drums | | 3 to 4 in. wide | 6 |
| 24 in. long | 5 | 4 to 6 in. wide | 7 |
| 30 in. long | 6 | Buzz planers, moulders, planers and all other machines having knives | |
| 36 in. long | 7 | Up to 6 in. long | 4 |
| 48 in. long | 8 | 6 in. to 8 in. long | 5 |
| 60 in. long | 10 | 8 in. to 12 in. long | 6 |
| Belt sander | | 18 in. to 24 in. long | 8 |
| Up to 4 in. wide | 4 | 24 in. to 30 in. long | 9 |
| 8 to 12 in. wide | 6 | Floor sweep-up | 6 |
| Disc sander | | | |
| Up to 24 in. diam | 5 | | |
| 24 to 36 in. diam | 6 | | |

book—Power, p. 1–81, forming Vol. 2 of this series. The main duct velocities average 3000–3500 ft. per min.

Average sheet-metal gages on blow pipe systems are as follows:

| Diameter, in. | Up to 5 | 6 to 8 | 9 to 15 | 16 to 24 | 25 to 32 | Over 32 |
|---|---|---|---|---|---|---|
| U. S. Gage No. | 26 | 24 | 22 | 20 | 18 | 16 |

The type of collector ordinarily used is the common cyclone. In most cases the fan blows into the collector, inasmuch as wood shavings are not particularly abrasive in action against the fan wheel.

**GRINDING, POLISHING AND BUFFING SYSTEMS** are another type of common blow pipe system. The general principles concerning design of hoods, ducts, etc., apply as in the case of planing mill exhaust systems, except that, ordinarily, higher suctions are required because the greater speed and the heavier particle tends to throw the dust out of the hood. Fig. 8 shows typical hoods used for abrasive exhaust systems.

Customary branch pipe sizes for various sizes of wheels are as follows:

| Wheel size, in. | 6–12 | 13–16 | 17–24 |
|---|---|---|---|
| Pipe diam., grinders, in. | 3 | 4 | 5 |
| Pipe diam., buffers, in. | 4 | 5 | 6 |

**TUMBLING BARREL EXHAUST SYSTEMS.**—Tumbling barrels ordinarily are equipped with dust outlets. Ducts are run to branches and to the fan accordingly. A minimum of 4000 ft. per min. air velocity should be provided from the vent opening. A preference would be 5000 ft. per min. Tumbling barrels are connected together like planing mill exhaust systems. The trunnion opening varies from 4 to 8 in., and the tumbling barrels are equipped with one or two trunnions. The common cyclone or cloth screen filter ordinarily is used to collect the dust.

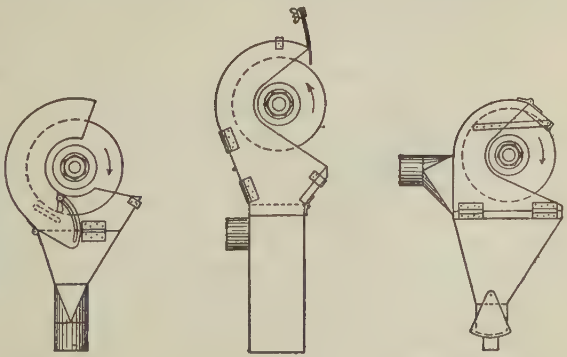

Fig. 8. Typical Hoods for Grinding and Buffing Wheels

**STATE LAWS.**—Particularly the states of Illinois, New York, New Jersey, New Hampshire, Michigan and Ohio have definite laws specifying either the pipe riser diameter, the suction at the hood, or the hood velocity or one or more of these elements. Some states specify no velocity, some specify 2 in. branch pipe suction, and some 5 in., whereas in some cases a flat specification of 9000 ft. per min. velocity is specified in the branches. State laws cover likewise the location of the collector, the size of the dampers and the design and arrangement of explosion relief vents. Some states specify that sheet-metal hoods are to be supplied at the points of dust production in granite and marble dust industries.

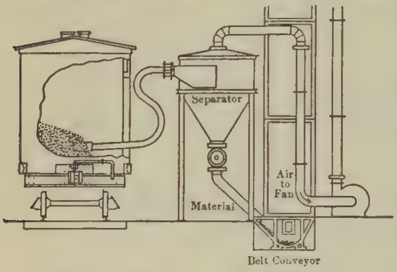

Fig. 9. Grain Unloading System

**PNEUMATIC CONVEYING.**—If a windstorm blows hard enough, solid particles are carried. The velocity of the air is a function of the size and weight of the suspended particle. To suspend a particle, the air thrust must equal the weight of the particle. Ordinary air at 4000 ft. per min. will exert a pressure of 5.2 lb. per sq. ft. The pressure is proportional to the square of the velocity. For conveying, air pressure must be greater than the weight of the material.

The critical air velocity is the vertical flotation velocity. Velocity for conveying the same material should be two to three times the critical velocity. The equation for the critical air velocity is, on the basis of standard air,

$$V = 3280\sqrt{(d \times \text{sp. gr.})}$$

where $V$ = critical velocity, ft. per min.; $d$ = diameter, in.; sp. gr. = specific gravity of the solid material. Critical velocity varies as the square root of the absolute temperature. At 600° F. the coefficient is 4640. Critical air velocities for common grains are as follows:

| Kind of grain | Wheat | Corn | Oats |
|---|---|---|---|
| Critical velocities, ft. per min. | | | |
| Lightest grains lifted | 1150 | 1350 | 800 |
| 50% of grains lifted | 1350 | 1600 | 950 |
| All grains lifted | 1500 | 2200 | 1150 |

**Pipe Carrying Capacity.**—The weight of material transported per pound of air varies directly as the square of the air velocity. Therefore, the carrying capacity of a stream of air increases directly as the cube of the velocity. The horsepower required to move the air varies also as the cube of the velocity; therefore the weight of the material moved is proportional to the fan horsepower. A 10-in. pipe, fed continuously at 5500 ft. per min. air velocity will handle 5 tons per hour. Capacity is proportional to area of the pipe.

Wheat can be transported with an allowance of 3.75 lb. of air per pound of material with a clean air velocity of 5000 ft. per min.

**Material Unloading Systems.**—Fig. 9 shows a common unloading system, such as is used for grain. Generally, such systems are not commercial when designed in connection with centrifugal fans. Since 2 to 3 lb. of air must be moved per pound of material, the efficiency of the system on the basis of the weight of the material moved, is low. The limit of suction of common centrifugal fans is 2 lb. per sq. in., which can be increased to 4 lb. per sq. in. by special design. Positive blowers (See Kent's Mechanical Engineers' Handbook—Power, p. 1–85, forming Vol. 2 of this series) are used at 6 to 10 lb. per sq. in. suction. They must draw through the collector, since the positive blower cannot handle material through its rotor. With such high suction, practically a full stream of material is pumped through the pipe. With high suctions, the pipe size is reduced considerably.

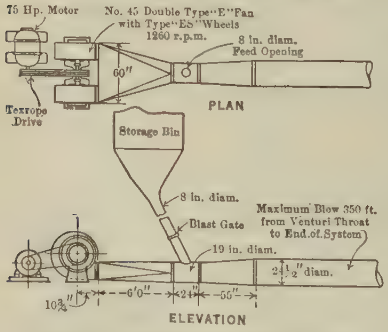

Fig. 10. Material Fed Beyond Fan

**Ducts for Conveying Cotton, Wool and Flax,** and other fibrous textile materials should be smooth inside and free from inward metallic projections. They should be made not less than 10 in. diameter to prevent stoppage. Duct velocity can be approximately 3000 ft. per min. with an allowance of 200 c.f.m. per pound of conveyed material. Stringy material that passes through the exhaust fan will clog up, unless cast-iron impellers are used. This type is cast in one piece and has smooth anticlastic surfaces, affording no points of adherence for stringy substances.

**Materials Subject to Damage by the Fan Impeller** are fed into the duct beyond the fan discharge. Fig. 10 illustrates such a system. The feeding pipe can be admitted at the throat of a Venturi in the fan duct to cause a siphoning from the storage bin.

## 4. CEMENT MILL DUSTS

**PRINCIPAL SOURCES** of dust are: 1. Grinding and handling clay and lime raw materials. 2. Pulverized coal for firing the rotary kilns. 3. Fly ash in the products of combustion from the rotary kilns. 4. Grinding calcined clinker. 5. Handling and bagging finished products. All these, except item 3, are collected by use of fan exhaust hood and piping systems, together with vortex collectors or cloth screen filters. When the air is highly laden with moisture, all piping, etc., should be well insulated to guard against condensation and the consequent plugging of the system. High duct velocities are advisable. Generous use of clean-out doors is necessary.

Fly ash is collected by vortex collectors, or electric, or spiral tube precipitators. Gas temperatures range from 400° to 1300° F., and contain a high percentage of $CO_2$. Materials of construction of the collector system should be chosen accordingly. When fly ash is collected at high temperature, the alkali content passes through the collector as a fume and consequently condenses when the gases strike the atmosphere.

Cement dusts are collected primarily on account of the health and nuisance factor, although they have a good recovery value. The fly ash contains about half calcined material which can be re-burned, unless high alkali content makes this inadvisable. Finished cement dust is especially valuable. Its greater fineness gives it superior strength.

## 5. BOILER FLY ASH

Size and quantity of ash discharged from boiler stacks depends on many factors, as: 1. Kind of firing, as stoker or pulverized fuel. 2. Percentage of ash in coal. 3. Kind of coal. 4. Ash fusion temperature. 5. Type of pulverizers. 6. Design of breeching, and heat exchangers. 7. Design of boiler. 8. Boiler rating, and other factors.

Conditions should be analyzed to determine whether to utilize a well proportioned drop box or settling chamber type collector; or whether to use the high-efficiency vortex collector, the spiral scroll collector, or the electric or spiral tube precipitator.

**Stoker-fired Boilers** may cause a flue gas dust concentration up to about 4 grains per cubic foot of gas. An average screen analysis of a typical sample, in which average combustible is 40%, and average weight is 40 lb. per cu. ft., is

| | | | | |
|---|---|---|---|---|
| Screen mesh ......... | 100 | 200 | 325 | 400 |
| Percent passed ....... | 52.8 | 36.8 | 28.4 | 20.4 |

This ash has a high local nuisance factor. Its relative coarseness causes rapid settling over a near, hence small, area. The nuisance concentration is high.

**Pulverized Fuel Fired Boilers.**—Dust concentration in flue gases varies from about 2 to 10 grains per cubic foot, depending on the percentage of ash in the coal, its fusion temperature, whether dry- or wet-bottom furnaces, design of boiler system, etc. A typical screen analysis is as follows, the sample containing 10% combustible and weighing 52 lb. per cu. ft.:

| | | | | |
|---|---|---|---|---|
| Screen mesh ........ | 100 | 200 | 325 | 400 |
| Percent passed ...... | 98.0 | 89.0 | 78.0 | 65.0 |

This dust can cause a nuisance a considerable distance away from the source, due to dust fineness. A given wind direction concentrates the pattern over an elliptical area. It is extremely abrasive to the induced draft fan wheel and housing. Dust collectors should be placed ahead of the fans. From a *fan maintenance standpoint* the flue gas temperature and fan static pressure are vital factors to determine advisability of the use of dust collectors. The fan wheel tip speed varies as the square root of both factors. Fan erosion varies exponentially with wheel tip speed. The exponent has been quoted as high as 9. With flue gas temperature around 450° F., fan erosion becomes potent above about 10 in. static pressure for stoker-fired boilers, and above 6 in. for pulverized-fuel-fired boilers.

From a *product standpoint*, fly ash or cinders practically are worthless. Aside from the fan maintenance angle, collectors are used to eliminate a nuisance.

**Required Collector Efficiency** depends on: 1. Proximity of nuisance-conscious neighborhood. 2. Height of stack. 3. Screen analysis of ash. 4. Quantity of ash. 5. Fan static pressure. 6. Money available.

Collectors which will remove 90–95% of the nuisance-range coarser particles, which results in an overall efficiency of 75–85%, should handle the problem satisfactorily.

# ILLUMINATION

## THE SCIENCE OF LIGHTING

**By Matthew Luckiesh**

The science and art of lighting may be divided for convenience into three major links: 1. Production of light; light-sources and their modifications. 2. Control of light; lighting equipment and installations. 3. Specification of light and lighting; foot-candle levels and lighting effects.

The first two links are means to certain complex ends. The third includes the efficiency, production, safety, comfort and welfare of human beings. The first link is a well-developed physical science quite beyond the realm of the designer and user of lighting. The second link also is a physical science dealing largely with optical facts and laws. The designer of lighting installations has been chiefly interested in this phase of the art of lighting. He chooses among the light-sources available, combining them and even modifying them for his purpose. However, the third link is the most important one for it not only completes the chain, but it largely determines the first two links. This link is a psychophysiological science, whose development lagged behind the first two. As a consequence, specifications of light and lighting have been largely a matter of guesswork, empirical at best. Besides, owing to the belated development of this link, the first two which are merely means to an end have received much more attention than the end itself.

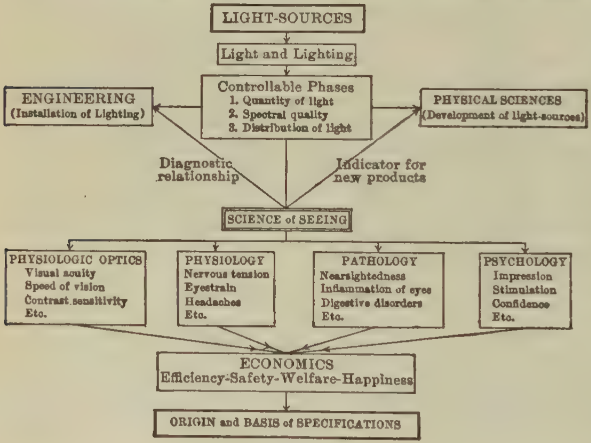

FIG. 1

The ultimate purpose of light and lighting is to make seeing possible. The ideal is to provide light in such amounts and lighting of such character that human beings can see most efficiently, effectively, accurately, quickly and safely. Therefore, specifications of light and lighting must be based upon a science of seeing. This involves a broader viewpoint and different concepts than the science of vision does. Eyes and light are mere tools and seeing is an activity of the entire human being operating as a human seeing-machine. See M. Luckiesh and F. K. Moss, The Human Seeing-Machine, *Jour.* Frank. Inst. ccxv, p. 629, June, 1933. The author and his colleagues, particularly Frank K. Moss, have been evolving this new viewpoint,* the science of seeing, and the researches arising therefrom are revolutionizing lighting considerations, particularly specifications. Fig. 1 illustrates the place of the science of seeing in the science and art of illumination.

**DEFINITIONS.**—A few important definitions (*Trans.* Ill. Eng. Soc., xxviii, p. 265, 1933) are as follows:

**Light.**—For the purposes of illuminating engineering, light is radiant energy evaluated according to its capacity to produce visual sensation.

---

* Seeing—A Partnership of Lighting and Vision, M. Luckiesh and F. K. Moss, Williams & Wilkins, Baltimore, 1931.

**Luminous Flux.**—Luminous flux is the time rate of flow of light.

**Lumen.**—The lumen is the unit of luminous flux. It is equal to the flux through a unit solid angle (steradian) from a uniform point source of one candle, or to the flux on a unit surface all points of which are at unit distance from a uniform point source of one candle.

**Luminous Intensity.**—Luminous intensity, of a source of light, in a given direction, is the solid-angular flux density in the direction in question. Hence, it is the luminous flux on a small surface normal to that direction, divided by the solid angle (in steradians) which the surface subtends at the source of light.

**Candle.**—The candle is the unit of luminous intensity. The unit used in the U. S. is a specified fraction of the average horizontal candlepower of a group of 45 carbon-filament lamps preserved at the Bureau of Standards, when the lamps are operated at specified voltages. This unit is identical, within the limits of uncertainty of measurement, with the International Candle established in 1909 by agreement between the national standardizing laboratories of France, Great Britain, and the United States, and adopted in 1921 by the International Commission on Illumination.

**Candlepower.**—Candlepower is luminous intensity expressed in candles.

**Foot-candle.**—The foot-candle is the unit of illumination when the foot is taken as the unit of length. It is the illumination on a surface one square foot in area, on which there is a uniformly distributed flux of one lumen, or the illumination produced at a surface all points of which are at a distance of one foot from a uniform point source of one candle.

**Brightness.**—Brightness is the quotient of the luminous intensity of a surface measured in a given direction divided by the area of this surface projected on a plane perpendicular to the direction considered.

**Reflection-factor (Reflectance).**—The reflection-factor of a body is the ratio of the light reflected by the body to the incident light. It is the sum of the regular and the diffuse reflection-factors.

**EFFICACY OF LIGHTING EQUIPMENT.**—Light-sources are rated in lumens per watt and in total lumens output. The efficiency of lighting equipment or an installation is the ratio of the lumens output to the total lumens produced by the light-source (or sources). The efficacy of lighting equipment or an installation is determined by its contribution to seeing accurately, quickly, safely and comfortably. This depends on many factors, such as the delivery of light to the work-place and to the surroundings, the location of the lighting equipment, the direction of dominant light, and the diffusion of light. The object of light is to produce brightness and the object of lighting is to reveal objects by highlights and shadows. The factors involved in the visual task are *size* of objects or details to be seen, *contrast* in brightness and color with their surroundings or background, *brightness-level* resulting from foot-candles and reflection-factor and *time* available for seeing.

**UNITS OF BRIGHTNESS.**—Inasmuch as brightness is a very important factor in seeing the following relations of Table 1 are presented.

**Table 1.—Units of Brightness**

1 lambert = 0.3183 candle per sq. cm. = 2.054 candles per sq. in.
1 candle per sq. cm. = 3.1416 lamberts.
1 candle per sq. in. = 0.4868 lamberts = 486.8 millilamberts.
1 spherical candlepower emits 12.57 lumens.
1 foot-candle = 1 lumen incident per sq. ft.
1 lux = 1 lumen incident per sq. meter.
*1 lambert = 1 lumen emitted per sq. cm.
*1 lumen emitted per sq. ft. = 1.076 millilambert.
*1 millilambert = 0.929 lumen emitted per sq. ft.

* Perfect diffusion is assumed.

**Surface Brightness** may be due to diffusely or specularly reflected light, or to a combination of both. The brightness of a surface which reflects light solely diffusely (a blotting paper) is due to the foot-candles and reflection-factor. The brightness of a surface which reflects light solely specularly (a perfect mirror) is due to the brightness of the image of something seen in the mirror. Therefore, the brightness of this surface depends on its reflection-factor but not on the foot-candles upon the surface. The brightness of a surface which reflects light both diffusely and specularly (such as common metal surfaces) is complex, and common considerations of foot-candles and reflection-factor are inadequate and erroneous. This is an important matter in lighting, which has been obscured generally by undue and improper attention to foot-candles. It is necessary to distinguish between light (foot-candles) and lighting (distribution of light, brightness, etc.).

**LIGHT-SOURCES.**—During recent years (1936 and prior), tungsten-filament lamps have been the most prevalent light-source in use. Their luminous efficiencies depend on size, wattage and use, ranging from 6 to 30 lumens per watt. The rating of the tungsten lamps most commonly used for general lighting purposes ranges from about 10 to 25 lumens per watt. However, since each year witnesses improvements, it is impracticable to present details.

Low-pressure mercury vapor arcs have been in use for a long time at about 15 to 16 lumens per watt. High-pressure mercury vapor arcs are coming into use (1936) at luminous efficiencies from 25 to 40 lumens per watt. Sodium vapor lamps are already operating at 50 to 70 lumens per watt. There is promise of still higher luminous efficiencies in these new vapor lamps.

Luminous efficiency is important. but the acceptability of a light-source for lighting also depends on other factors, such as physical size, wattage, auxiliary equipment, color and spectral character of light, and obvious economic factors.

**LIGHT-CONTROL.**—In lighting equipment and installations, control of light is achieved by various kinds of media having such optical properties as opacity, refraction, diffuse transmission, and specular and diffuse reflection. Besides the use of optical systems of mirrors, lenses, prisms, etc., for special purposes, simple lighting equipment involves one or more of the foregoing optical characteristics. Polished metal and prismatic glass reflectors and other devices are widely used for light control. Equipment for general lighting may consist of metal reflectors with various degrees of specularly or diffusely reflecting surfaces. Various distributions of light are obtainable by altering the shape and surface finish. Much general lighting equipment consists of diffusely transmitting glass, large enough in relation to the lumens output to prevent the surface brightness of the glass from being too great to be annoying, even in the peripheral field of vision. The brightness of a cloudless sky commonly varies from 1 to 4 candles per square inch, and this range may be taken as the desirable upper limit of brightness in the field of view. A sunlit cloud may have a brightness as high as 20 candles per square inch. This is too bright for comfort indoors under the conditions of low foot-candle levels and brightness levels.

**GENERAL AND LOCALIZED LIGHTING.**—Lighting should be divided into general lighting for general purposes and localized lighting for specific purposes. General lighting is accomplished by indirect and direct systems, by a combination of both, or by an equivalent of such a combination. Indirect lighting requires a reflecting surface, as a ceiling. In a special case the wall or its equivalent may be used. By this method, the bright light-sources and bright areas of the lighting equipment are entirely concealed. However, a wide expanse of bright ceiling or other area may be annoying and may reduce the ability of a worker to see. In large rooms this is not necessarily ideal. It is merely better than a direct-lighting system in which very bright sources or surfaces of lighting equipment are in the field of view.

Resort usually must be made to direct lighting where there is no ceiling available, or where the reflection-factor of the ceiling cannot be maintained properly. Metal or glass reflectors or shades can be of such shape and height that workers cannot conveniently see the surfaces of the equipment which usually are unduly bright.

Between purely indirect and direct systems there are many which are carelessly cataloged as semi-indirect lighting. Glass reflectors in direct-lighting systems permit some light to escape to the upper surroundings and ceiling. Even this low brightness adds much to the satisfactoriness of the lighting. Metal reflectors have been perforated at the top, or are hung on diffusing glass envelopes in such a manner that some light escapes upward. At the same time the light-source is so concealed that the visible brightness of the fixture is reduced to a reasonable limit. This glassteel fixture has been quite satisfactory in many factories. In offices, and in many clean factories with painted walls and ceiling, simple fixtures of diffusely transmitting glass, entirely enclosing the light-source, commonly are used. This is termed direct lighting, notwithstanding the fact that nearly as much light is emitted upward as downward.

Fixtures for general lighting are best appraised by the percentages of light emitted generally upward and downward, respectively. This not only makes it possible to design or choose them wisely for a given interior, but also gives an idea of the lighting effect which they will produce in any interior.

**SPECIFICATION OF LIGHT AND LIGHTING** is the third link in the chain and is the important one. It can be divided into three parts: 1. Quality of light; color and spectral character. 2. Quantity of light; foot-candles and brightness. 3. Quality of lighting; distribution of light, brightness, etc.

**QUALITY OF LIGHT.**—The color of light is not necessarily an indication of its spectral character, although the latter always is an indication of the former. The color of light is important from a psychological viewpoint. Spectral character may be important from the viewpoint of vision in special cases. Daylight is white or bluish-white in color. Psychologically it is associated with work and with daytime. For this reason a white light may seem to be a better light for work-places although there is not yet available any scientific proof of this. Nevertheless human beings, having evolved outdoors, probably are best adapted to white light of a continuous spectrum.

It has long been known that strictly monochromatic light (of a narrow range in wave length) is focused more definitely by a simple lens, such as the eye system, than light of an extended spectral range. Of the unmodified illuminants available at present, sodium light is the only approximately monochromatic light available. Visual acuity, or the ability to distinguish fine detail near the threshold in size visible, is higher under sodium light than it is under the same brightness of light of extended spectral character.[*] This fact can be taken advantage of in special cases, but it should be noted that the size of details to be seen ordinarily is much greater than threshold or near-threshold size. Only near the threshold in size is visual acuity important. Besides, it should be noted that under monochromatic light all color, excepting that of the illuminant, disappears and all the advantages of color-contrast are lost. Extensive studies of this monochromatic light have been made without revealing any other advantages, excepting higher visual acuity at the size threshold, over light of an extended spectral character.

Similar studies have been made with mercury vapor light and no advantages among the complex factors of seeing have been revealed. Even visual acuity is no greater under mercury light than under continuous-spectrum light. Owing to its discontinuous spectrum, colors are distorted under mercury light. A combination of light from high-pressure mercury arcs and tungsten-filament lamps provides a satisfactory psychological white light without much distortion of colors. This combination utilizes the high efficiency of these mercury arcs and may be used extensively in the work-world on account of its whiteness.

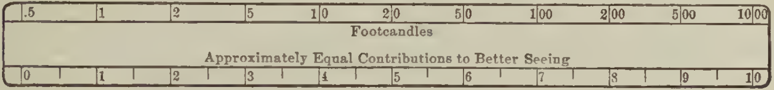

Fig. 2. The Relation of Foot-candles to their Effectiveness

Thus it is seen that excepting from a psychological standpoint and the appearance of colors, scientific knowledge at the present time does not reveal spectral character as of primary interest in lighting. Therefore, the choice of an illuminant should be based on certain other factors, such as luminous efficiency, convenience, cost, and the expense of maintenance.

**FOOT-CANDLES AND FOOT-CANDLE-LEVELS.**—The foot-candle defined as a physical unit is constant in value. In actual use, as an aid to seeing, it is not constant. One foot-candle added to one foot-candle effectively increases the ability to see, but when one foot-candle is added to 10 or 100 foot-candles its contribution to seeing is negligible. In considering the application of foot-candles for their effectiveness in promoting better seeing it is essential to realize that the foot-candle-level must be doubled in order to obtain an obvious and significant improvement in seeing. This leads to the suggestion that foot-candle levels be established in round numbers as shown in Fig. 2. These geometric steps in foot-candles correspond to arithmetic steps in effectiveness upon seeing. Furthermore, this emphasizes the practicability and desirability of establishing a series of foot-candle-levels. Then by experience and actual measurement of visibility of objects and tasks, various tasks of the work-world may be classified in the appropriate foot-candle-level.

There are two fundamental foot-candle-levels. The first and obvious one is that of barely seeing to perform a given visual task. This is the **threshold foot-candle-level.** For example, one possessing normal vision can read a newspaper or even a machinist's scale under a fraction of a foot-candle if given enough time, and if the penalties to eyesight and other human resources are ignored. Studies of vision as a tool reveal only these threshold conditions. Lighting practice has been based largely upon this misconception, and foot-candle specifications have been influenced by this narrow viewpoint.

To escape from this confined view, seeing must be considered instead of vision. Seeing is an activity of the human being operating as a seeing-machine. Seeing is work done by the human seeing-machine. This viewpoint greatly broadens the considerations of aids to seeing such as foot-candles. It reveals another foot-candle-level *i.e.*, that for *easiest* seeing for a given visual task. Investigations designed to ascertain this level for various tasks involve studies of the relations of foot-candles to various physiological and psychological effects resulting from performance of the work of seeing. This fundamental level is that at which the human seeing-machine sees most easily, accurately, and quickly. These are the objectives of the science of seeing. This ideal foot-candle-level already is known to be of a different order of magnitude from that for barely seeing.

---

[*] Seeing in Sodium-Vapor Light, M. Luckiesh and Frank K. Moss, *Jour.*, Op. Soc. of Amer. xxiv, p. 5, 1934.

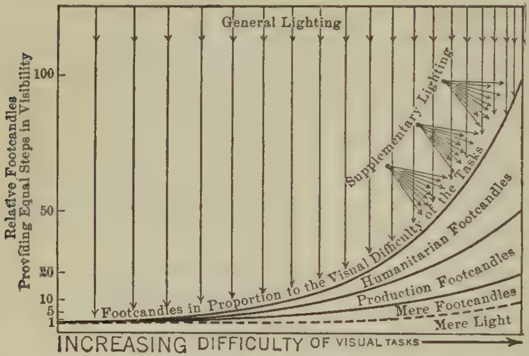

FIG. 3. Relation of Illumination to Difficulty of Visual Tasks

In general, it is indicated to be comparable with daylight levels of illumination. These are hundreds and even thousands of foot-candles. On a sunny day in summer there are commonly 1000 foot-candles in the shade and 8000 to 9500 foot-candles in direct sunlight. Indoors at the window sill there are commonly 100 to 300 foot-candles. At the work-places indoors under natural or artificial light as practiced at present there is an average of less than 5 foot-candles. Artificial light was invented as a competitor of darkness, and the science of vision did not rescue its practice from this basis of barely seeing. The science of seeing reveals that it should be a competitor of daylight. This is so revolutionary that past lighting practice is of little use as a guide.

Fig. 3 illustrates the evolution of the practice from primitive lighting to scientific specification of foot-candles for easy seeing. The vertical geometric scale deals with relative foot-candles from the proper viewpoint of effectiveness. The horizontal scale is one of increasing difficulty of the visual task. For centuries, mere light was available from a light-source near the worker. With the development of gas and electric lighting, mere foot-candles were supplied to entire work-areas. Next came the recognition that the production of the worker was influenced by foot-candles up to a certain level. Finally the science of seeing began to indicate the ideal levels for easiest seeing. These levels of hundreds and even thousands of foot-candles can be obtained economically by general lighting plus supplementary lighting as indicated on the diagram.

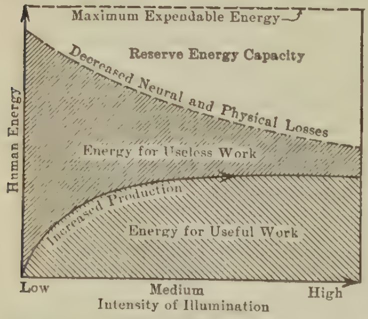

FIG. 4. Relation of Illumination to Production

**Production of Workers.**—Carefully performed studies reveal that the production of a worker ceases to increase appreciably after a level of 20 or 30 foot-candles is reached. Actually in naturally performed work in carefully controlled researches, the rate of work done has been found to increase gradually as the level is increased to at least 100 foot-candles. However, these slight increases usually are not of much practical importance. Before the new concepts and viewpoint of the science of seeing entered into lighting considerations, production was assumed to be an important measure of the beneficence of foot-candles. This is not true, for it has been adequately proved that the production of a worker may be practically the same for two tasks differing greatly in visual difficulty and, therefore, in their drain upon the human resources of the worker.

Fig. 4 illustrates the relation between illumination and the expenditure of human energy. This is necessarily diagrammatic, because it is impossible to give numerical values to the ordinates. As the intensity of illumination increases, production increases along the typical curve indicated. Eventually it reaches a practical maximum. From the viewpoint of narrow economics, the efficiency of the worker is measured in the amount of work done per dollar, or per hour. However, the true efficiency of the worker as a human seeing-machine is the ratio of energy expended for useful work to the total energy expended. As the foot-candles are increased beyond the point where the useful work of the worker ceases to increase appreciably, the work is done more and more easily as indicated. Considerations of this sort lead to the conclusion that humanitarian foot-candle-levels are far higher than production-levels. This diagram is supported by many data pertaining to the costs of seeing to the human seeing-machine.

Light and lighting are always factors in seeing, but there are other factors. Seeing is complex, but it can be divided into at least three parts, all of which are important to the human seeing-machine. These are: 1. The visual tasks or things to be seen; 2. The visual sense as a tool, and as a doorway to the consciousness; 3. The internal realm of psychophysiological effects of seeing. This is a complex chain leading from the visual tasks to the end-products of human efficiency, behavior and welfare. Light and lighting are controllable factors which influence the ease or difficulty of the visual task. They should be fitted to the eyes involved. They generally can aid subnormal vision even more than they aid normal vision. They deeply influence the physiological effects of seeing as far removed from the eyes as the far-reaching effects of food are removed from the stomach. This view reveals the futility of eyes and human beings as capable judges of the effectiveness of foot-candles above the threshold level of barely seeing. The human being needs dependable aids for determining foot-candle requirements for various tasks. And these must be founded upon a science of seeing.

**RECOMMENDED FOOT-CANDLES.**[*]—Foot-candle specifications necessarily have been empirical, and in many cases have been unnecessarily inconsistent. There has been no rational basis until recently (1936). The indicated ideal foot-candle-levels for easiest seeing are so far above those for barely seeing that in many cases they cannot be obtained by prevalent lighting methods at acceptable costs at the present time. For various reasons, compromise is necessary, but this is common in engineering. However, foot-candle specifications can be consistent if based upon equal visibility. In addition to this the Luckiesh-Moss visibility meter [†] makes it possible to specify foot-candles for various visual tasks on a rational basis. This device takes into account important factors of the visual task such as size, contrast and brightness, and also the visual sense of the user.

In Table 2 an attempt has been made to provide by brief description an example of foot-candle specifications for all the common tasks of the work-world. These are ultra-conservative.[‡] They are frankly a compromise between optimum values and prevalent values, or those obtainable by available lighting equipment and present lighting methods. However, these recommendations take into account the geometric scale of foot-candle effectiveness, the effects upon visibility of such factors as size, contrast and brightness, and other new concepts and knowledge embodied in the science of seeing. They are consistent and rational, and, therefore, represent a great improvement over the primitive and unnecessarily poor conditions for seeing which are prevalent throughout the indoor world in the daytime and everywhere at night.

**Table 2.—Foot-candle Specifications for Various Classes of Work**

**100 Foot-candles or More.**—For very severe and prolonged tasks, such as fine needlework, fine engraving, fine penwork, fine assembly, sewing on dark goods and discrimination of fine details of low contrast, as in inspection.

**50 to 100 Foot-candles.**—For severe and prolonged tasks, such as proof-reading, drafting, difficult reading, watch repairing, fine machine work, average sewing and other needlework.

**20 to 50 Foot-candles.**—For moderately critical and prolonged tasks, such as clerical work, ordinary reading, common bench work and average sewing and other needlework on light goods.

**10 to 20 Foot-candles.**—For moderate and prolonged tasks of office and factory and, when not prolonged, ordinary reading and sewing on light goods.

**5 to 10 Foot-candles.**—For visually controlled work in which seeing is important, but more or less interrupted or casual and does not involve discrimination of fine details or low contrasts.

**0 to 5 Foot-candles.**—The danger zone for severe visual tasks, and for quick and certain seeing. Satisfactory for perceiving larger objects and for casual seeing.

**VISIBILITY AND FOOT-CANDLES.**—The difficulty of performing visual tasks arises from such factors as size of critical details, contrast of these with their surroundings or background, and brightness due to the effects of foot-candles and reflection-factor. The threshold size that average normal eyes can see under a few foot-candles if the contrast is high, as black on white, is about 1 minute visual angle. This corresponds to about 0.004

---

[†] Visibility—Its Measurement and Significance in Seeing, M. Luckiesh and Frank K. Moss. *Jour.* Frank. Inst. ccxx, p. 431, 1935.

[‡] Seeing and Human Welfare, M. Luckiesh, Williams & Wilkins, Baltimore, 1934.

in. at a distance of 14 in., or the width of a man a mile distant. Excepting in special cases, human seeing-machines ordinarily are not obliged to see objects so near the size threshold. The science of seeing reveals that for sizes larger than 3 minutes visual angle, contrast becomes the more important factor in visual tasks. With these factors commonly fixed in visual tasks, brightness can be increased, with the result that visibility can be controlled to a large degree. If the object can be viewed against a removable background, the latter can be made of high reflection-factor. This requires fewer foot-candles than a background of low reflection-factor for a given brightness. In relatively rare cases a dark background is expedient. In these the brightness of the object can be increased by increasing the foot-candles.

For example, large telephone directories necessarily are printed on thin, inexpensive paper, whose reflection-factor is lower than that of good white paper. Besides, the contrast between the print and paper is lower than in the case of excellent printing of the same type on thicker white paper. The result is that about three times the foot-candles are necessary for equal visibility of the same text in the telephone directory as in a well-printed book.

Clerical work varies enormously, but, in general, the visual tasks involve high contrast. In official codes of foot-candle specifications it has been the practice to recommend only twice the foot-candles for sewing on dark goods as for office work, notwithstanding the low contrasts between thread and textile in the former case. From the sole consideration of brightness, the garment worker commonly should have at least 10 times the foot-candles of the office worker. This same principle applies through the work-world in fine assembly, inspection, etc.

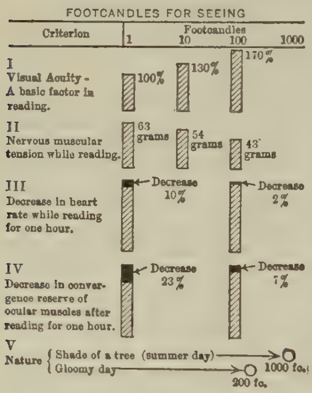

Fig. 5. Criteria for Ascertaining Relation between Foot-candles and Ease of Seeing

The science of seeing includes correlations between visibility and ease of seeing. Such factors as shown in Fig. 5 are taken into account.* It is evident that the task of reading not only is made easier by higher levels of illumination, as indicated by item I, but also the hidden penalties are minimized, as indicated by items II, III, and IV. The decrease in nervous muscular tension with increase in foot-candle level means less energy wasted and less bodily and mental fatigue. It should be noted that this task of reading books printed in large type (10- and 12-point) could be done under a small fraction of a foot-candle (the threshold foot-candle-level). The level for easiest reading is apparently above 100 foot-candles. And this is a relatively easy task compared with those involving very fine details and low contrasts. Even the heart-rate (item III) is affected by this relatively easy task and is more nearly normal under 100 foot-candles than under a few foot-candles. Item IV shows that fatigue of certain eye-muscles decreases with increases in foot-candle-level. These, and other researches and correlations, have definitely established that the optimum visibility of details of a black object on a white background is obtained under a level of illumination well above 100 foot-candles.

**The Luckiesh–Moss Visibility Meter** has two rational scales, viz., 1. Relative visibility; scale range, 1 to 20. 2. Foot-candles recommended; scale range, 1 to 1,000. In all the researches and calibration tests upon which these scales are based, subjects with average normal vision were used. Therefore, other factors being equal, the meter is also a practical test of the part that subnormal vision may play in everyday seeing.

The visibility scale has an absolute rational basis founded upon the maximum ability of persons with average normal vision to recognize the details of a simple describable object of definite size and contrast. In an absolute sense, a setting at unity on the visibility scale represents the limit of average normal vision under favorable conditions for seeing. The scale value 2 indicates that the object or task is twice as visible as the smallest object which can be recognized by persons with average normal vision. These scale values not only represent relative visibility of objects or visual tasks, but also can be interpreted as factors of safety in seeing.

The scale values of recommended foot-candles have no obvious relation to the scale values of relative visibility. The former are rational among themselves in a relative sense. However, the actual values are an arbitrary compromise between the foot-candles necessary for barely seeing and the enormously higher foot-candle levels for easiest seeing, as indicated by researches in seeing. That the scale of recommended foot-candles is conservative is attested by the fact that it is based on the visibility of reading matter printed with 8-point type and black ink on excellent white paper, and illuminated to an intensity of 10 foot-candles without any preventable glare present. This task corresponds to the scale value 10. Researches in several directions have indicated that at least 100 foot-candles are desirable for that particular visual task. A scale value of 20 for another task under the same intensity of illumination as the former basic task indicates that it should have 20 foot-candles in order to be as visible or as easily performed as the foregoing standard task (8-point black print on white paper at 10 foot-candles).

---

* The New Science of Lighting, M. Luckiesh and Frank K. Moss, *Trans.* Ill. Eng. Soc., xxix, p. 641, 1934.

If all visual tasks are studied with the visibility meter at the standard level of 10 foot-candles, the scale reads directly the recommended foot-candles whose actual values are an arbitrary compromise between ideals and practical engineering and economic factors. In practice when the actual ($A$) foot-candles on the task being studied differ from 10 foot-candles, the scale reading of recommended foot-candles should be multiplied by the ratio $A/10$ or $0.1\,A$ to obtain, with sufficient accuracy, the true value of recommended foot-candles for that particular task. Wherever practicable in studies of foot-candle requirements for various visual tasks, a standard intensity of illumination of 10 foot-candles should be used so that the recommended foot-candles can be read directly from the scale. The basic principles underlying the scales of the instrument have been described in detail elsewhere.*

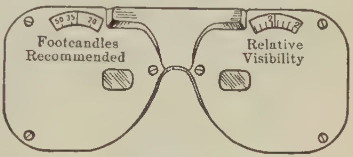

Fig. 6. Visibility Meter

Special gradient filters are turned until the user is barely able to perform various tasks. Properly used, recommended foot-candles can be read from the scale for various tasks in order that the latter may be of the same visibility as the basic task. Table 3 shows the foot-candles necessary to render the various tasks of equal visibility.

**Table 3.—Foot-candles Required for Equal Visibility**

| Visual Task | Foot-candles for Equal Visibility |
|---|---|
| Excellent printing | |
| 8-point Bodoni type | 10 |
| 6-point " " | 17 |
| 10-point " " | 7 |
| 12-point " " | 5 |
| Handwriting with pencil | 25 |
| Newspaper text matter (approximately 8-point) | 35 |
| Telephone directory—yellow pages | 55 |
| Shorthand notes in pencil | 60 |
| Reading micrometer | 70 |
| Typing on dark blue paper | 75 |
| Newspaper—stock quotations | 80 |
| Reading steel scale $^{1}/_{64}$ in. divisions | 150 |
| Distinguishing black thread on dark cloth | 500 |

If a higher or lower basic visibility is desired, the transformation is easy. Table 3 shows the 8-point type to require twice the foot-candles that the 12-point does for equal visibility. If the basic degree of visibility is desired to be that represented by 10 foot-candles on 12-point type, all the foot-candle values in the table are doubled. The visibility meter not only renders foot-candle specifications consistent with the visibility of visual tasks on a definitely rational basis, but it introduces the idea of factors of safety into lighting practice.

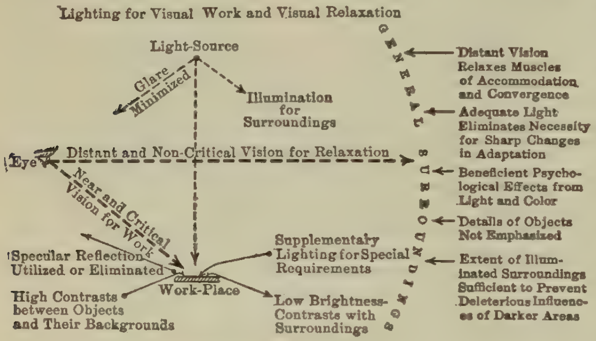
There are numberless visual tasks and many fields of lighting. Most tasks are not accurately describable. Therefore, in Table 3, only a few of the describable ones are presented. Foot-candle specifications can be obtained readily for any task. These eventually will appear in the publications which guide lighting practice. In many lighting fields there is a variety of tasks. By means of visibility measurements a compromise foot-candle-level may be recommended. It appears most practicable to place specific tasks and specific lighting fields in one of ten or more foot-candle-levels on a geometric scale as suggested on p. 26–15. This has not yet been done (1936), and therefore, no official foot-candle specifications can be presented for the many work-world tasks and activities.

---

* Visibility, Its Measurement and Significance in Seeing, Luckiesh and Moss, *Jour.* Frank. Inst. Vol. 220, 1935, p. 431.

**QUALITY OF LIGHTING** involves the distribution of light and brightness in the visual field. It has much to do with the visibility of three-dimensional objects, with fine detail on specularly reflecting surfaces, with the psychophysiological effects of glare and of brightness of surroundings compared with that of the work to be performed. For fine work, involving the visibility of objects of three dimensions, there can be no question that a dominant source of light, well-screened from the eye, is important. If the objects are mobile, they are manipulated in the hands while the worker produces the lighting effect enabling him to see. This effect may be a high light, or shadow, or a silhouetting of the object against the proper background. In general, any lighting problem may be divided into two parts: 1. Lighting the task or central work-field; 2. Lighting the surroundings. The former requires high intensities for high visibility of the work. In the work-field, physiological factors of seeing predominate. In the surrounding field, the psychological factors predominate. However, both are complexly related.

In Fig. 7 the major factors of the problem of lighting for seeing are shown diagrammatically. Quality of lighting is a complex summary, involving all that is seen in the work-field and in the surroundings. A simple summary is impossible, but Fig. 7 should be helpful. The present designation of lighting equipment and installations is inadequate from the viewpoint of lighting for seeing. Their effect upon seeing and upon human beings depends on the distribution of brightness in the central and peripheral fields. This in turn depends on the size of the interior, reflection-factors, characteristics of the visual task and other factors. Although it has been adequately proved that a human being is a very poor seeing-meter and therefore a poor appraiser of lighting conditions, anyone with experience can recognize the more undesirable characteristics of poor lighting. However, any appraisal of a lighting condition without actually performing the tasks for a long period may be misleading.



Lighting for Visual Work and Visual Relaxation
Light-Source
Glare Minimized
Illumination for Surroundings
Eye
Distant and Non-Critical Vision for Relaxation
Near and Critical Vision for Work
Specular Reflection Utilized or Eliminated
High Contrasts between Objects and Their Backgrounds
Work-Place
Supplementary Lighting for Special Requirements
Low Brightness-Contrasts with Surroundings
Distant Vision Relaxes Muscles of Accommodation and Convergence
Adequate Light Eliminates Necessity for Sharp Changes in Adaptation
Beneficient Psychological Effects from Light and Color
Details of Objects Not Emphasized
Extent of Illuminated Surroundings Sufficient to Prevent Deleterious Influences of Darker Areas

FIG. 7

Eye-fatigue is measurably greater under purely localized lighting than it is after general lighting has been added. Such an extreme also is annoying in various ways. It is unsafe when workers are exposed to dangers due to poor seeing. On the other hand, in large interiors purely general lighting is the other extreme, which may be annoying and even uncomfortable in the same way as purely localized lighting, but usually not to such a noticeable degree. Safety and comfort demand general lighting but maximal efficiency, generally is realized by adding suitable localized lighting to satisfactory general lighting.

The balance between the general and supplementary lighting not only is important, but is a valuable tool in obtaining adequate light and proper lighting. By properly balancing the two components, high foot-candle-levels can be satisfactory. By adding supplementary lighting to general lighting, various advantages to seeing can be utilized; hundreds of foot-candles can be obtained at low cost; and even 1000 or more foot-candles become economically possible.

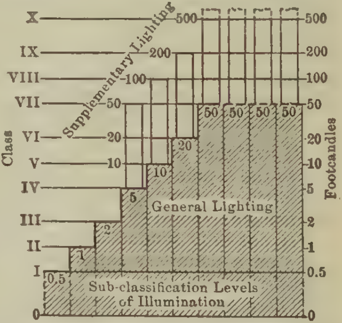


FIG. 8. Combination of General and Supplementary Lighting

Fig. 8 shows safe combinations of general and supplementary lighting for various foot-candle-levels. When and where localized lighting is to be added to general lighting depends upon many factors, too complexly interwoven to discuss here. The foot-candles supplied by supplementary lighting are shown to a limit of ten times the foot-candles supplied by general lighting. The reflection-factors of the work and of the surroundings are important. Here, painting of machinery, walls and ceiling can play an important part.

# SAFETY ENGINEERING *

By Sidney J. Williams

## 1. ACCIDENT PREVENTION

The guarding of dangerous machinery and other dangerous places is required by the laws of most states. The absence of such protection generally is penalized, also, by an increase in the rate charged for workmen's compensation insurance.

Many industrial concerns endeavor to eliminate or guard all danger points and to correct all unsafe practices, even where not demanded by state or insurance regulations, because they have found that: 1. Accidents cause, or indicate, an irregularity in production which results in lost time and inefficiency. 2. Accidents cause the temporary or permanent loss of experienced and valuable workmen. 3. Careful attention to safety, by both mechanical and educational means, raises the morale of the working force. Such companies often require that equipment which they purchase be guarded in accordance with certain specifications.

**STANDARDS FOR SAFEGUARDING.**—There has been a considerable lack of uniformity in the requirements of various state and insurance authorities; this is being gradually overcome through the formulation of standard safety codes under the auspices of the American Standards Association (29 West 39th St., New York City). The specifications outlined below are those which generally prevail; the State Department of Labor or State Industrial Board, and the insurance company carrying the risk should be consulted for additional or (in a few cases) more stringent requirements.

**THE ESSENTIALS OF AN EFFICIENT SAFEGUARD,** according to the National Safety Council are: 1. It should be so designed and constructed that it will prevent, on the part guarded, all accidents both to the operator at his regular work and to others who may slip, fall or carelessly touch the machine.

2. It should not interfere with production. If it does, it is liable to be removed. In designing a guard, it generally is wise to consult the man who will use it.

3. In general, it should be attached to the machine. If attached to the floor, use a connection which will interfere as little as possible. See Fig. 1.

4. The guarded part must be easy of access for oiling, inspection and repair, through a door or removable section hinged or fastened to the body of the guard, or to the machine. If not attached, it is likely to be left off permanently.

5. The guard should not interfere with cleaning and sweeping around the machine. It, therefore, should be kept usually about 6 in. above the floor.

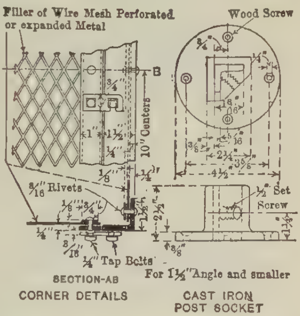

FIG. 1. Details of Machine Guard

6. The guard should be strong enough to resist injury and keep its shape. A light, flimsy guard soon becomes bent and is discarded. A substantial guard is cheaper in the end.

7. Incombustible guards are preferred; except, where subjected to acid fumes, wooden guards may be necessary. Wooden guards, soaked with oil, may become a serious fire hazard. Guards may be made of cast iron, sheet metal, wire mesh, expanded or perforated metal, or slats.

8. The guard and operating mechanism should interlock where possible, to prevent the machine operating unless the guard is in place.

9. A safeguard often can be so designed as to prevent wear on the parts guarded—for example, a solid gear enclosure.

## 2. MECHANICAL POWER TRANSMISSION

**GEARS, FRICTION DRIVES, SPROCKETS.**—"All gears and friction drives, wherever located, shall be completely encased, or, where this is impracticable, shall have a continuous band guard provided with side flanges extending inward beyond the roots of the teeth. All sprockets, wherever located, shall be completely encased. Chains shall be guarded as prescribed for belts. Where there is a spoke hazard, gears and sprockets shall always be enclosed on exposed side."

---

* In this section the material included in quotation marks is taken from the Rating Schedule Standards used by most insurance companies and rating bureaus.

Cast-iron guards are preferable, as they fit snugly, present a good appearance and protect the gears from dust and injury. Guards for a variety of machines, and in many sizes, may be more cheaply made of sheet metal. In large guards, an angle iron is used to make the joint between the flat sides and the curved part of the guard. In smaller guards this joint may be made by cutting projections (like saw teeth) on each side piece and bending these over to form a smooth curve. The joint may then be made by spot welding or riveting. Pieces of angle iron $^3/_4 \times {}^3/_4 \times {}^1/_8$ in., 1 in. long, spaced 3 in. to 4 in. apart, may also be used to form the joint.

**FRICTION CLUTCHES.**—"Any revolving part of a friction clutch having dangerous projections within 7 ft. of the floor or platform shall be completely and substantially encased. This also includes any clutch on transmission shafting that is used as the starting and stopping device of a machine, if any part of the clutch has dangerous projections which revolve when the machine is stopped."

**BELTS, CHAINS AND ROPES.**—"If vertical or inclined, 6 ft. or less; if horizontal, with lower run 7 ft. or less above floor or platform, shall be guarded as shown in Figs. 2, 3, 4 and Table 1.

"Where both runs of a horizontal belt are within 6 ft. 6 in. of floor level, the guard shall extend at least 15 in. above the belt, or to a height of 6 ft., but in no case shall it be less than 42 in. high, unless the belt is completely enclosed. Overhead horizontal belts with lower run 7 ft. or less from floor or platform level, shall be guarded on bottom and sides to a height of not less than 6 in. above the lower run of the belt, but not over 7 ft. above the floor. Where pulleys are of such dimensions and so located as to permit passage between the upper and lower runs of horizontal belts, standard railing shall be provided, and a substantial passageway, guarded on both sides and top shall be constructed, or all space completely barred against passage."

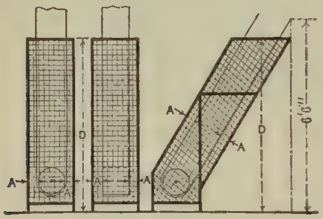

FIG. 2. Belt Guards

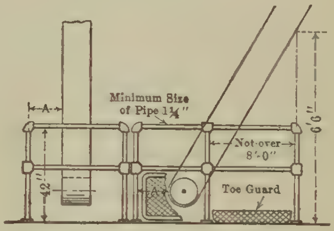

FIG. 3. Belt Guard Using Railings

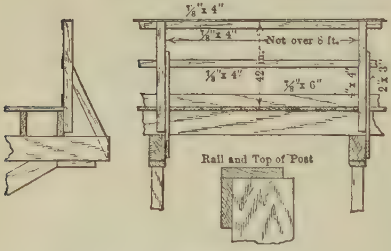

FIG. 4. Wooden Railings

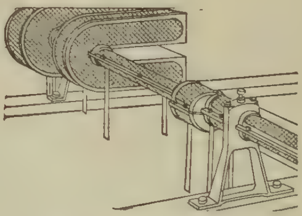

FIG. 5. Shafting Guards

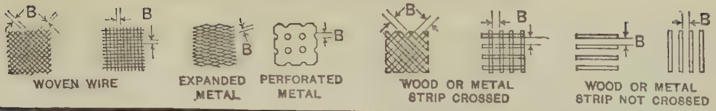
**SHAFTING.**—"Vertical and inclined shafts shall be encased with stationary guards to a height of 6 ft. from floor or platform level. Horizontal shafting, less than 6 ft. from the floor or platform level shall be completely encased . . . or protected by a trough enclosing sides and top or sides and bottom as location requires." See Fig. 5. "Railings are not acceptable as guards for shafting."

**SHAFT ENDS.**—"Any exposed shaft end, which projects beyond a bearing or hub more than 2 in. and is within 6 ft. of the floor or platform, shall be cut off or completely enclosed."

**PROJECTIONS ON REVOLVING SHAFTS.**—"The following are dangerous projections and require protection wherever located: 1. Set-screws, keys, bolts, oil cups or similar projections when not within the plane of the rim of a pulley. 2. Couplings containing protruding bolts or nuts. 3. Broken pulleys and other similar projections.

**Table 1.—Belt Guard Clearances**



| Material | Minimum Clearance of Belt, in. *A* | Largest Mesh or Opening, in. *B* | Minimum Thickness | | Minimum Height of Guard from Floor or Platform, ft. |
|---|---|---|---|---|---|
| | | | In. | U. S. Std. Gage No. | |
| Woven wire | Under 4 | 1/2 | .... | 16 | 6 |
| | 4–15 | 2 | .... | 12 | 5 |
| Expanded metal | Under 4 | 1/2 | .... | 18 | 6 |
| | 4–15 | 2 | .... | 13 | 5 |
| Perforated metal | Under 4 | 1/2 | .... | 20 | 6 |

* Wood. † Metal. ‡ Maximum clearance.

4. Gears, pinions or sprockets on transmission shafting which are not meshing with other gears or carrying a chain."

"Pulleys, not carrying belts but with spokes or projections, even if these are within the plane of the rim of the pulley, shall be considered dangerous projections when within 6 ft. of floor or working platform."

"All projecting keys in revolving shafts shall be made flush or protected with cylindrical safety sleeves or by stationary enclosures. All revolving objects which project beyond the plane of the rim of pulley, gear or wheel shall be guarded by cylindrical safety sleeves, metal discs or by stationary enclosures. All revolving set-screws exposed to contact shall be made flush or countersunk beneath the surface of the metal part in which they are inserted."

**BELT SHIFTERS.**—"Each set of tight and loose pulleys shall be provided with a belt shifter. This shall be understood to mean a permanent mechanical device by means of which the belt may be shifted from one pulley to the other without touching the belt with the hand."

**INDIVIDUAL AND GROUP DRIVES.**—Certain processes of manufacture lend themselves to individual machine drives, thus eliminating transmission and the dangers of its use and repair. The lighting of a working place is improved by the absence of overhead transmission.

Group drives do not eliminate transmission but they do reduce the danger of running on belts, making repairs and adjustments, etc., since the machines in the group can be shut down easily for the moment needed for such work.

Individual drives, group drives or power control systems make it possible to shut down machines quickly in an emergency.

Also see Safety Code for Mechanical Power-Transmission Apparatus, Am. Stds. Assoc.

## 3. GENERAL MACHINERY

In addition to the guarding of belts, gears, etc., as described above, and the guarding of points of operation described below, safety requires machines to be so located that each workman will have sufficient space in which to handle his material with the least possible interference from other workmen or machines. Machines never should be so located that it is necessary for operators to stand near an aisle, or so that two operators are likely to interfere with each other. Aisles should be maintained of sufficient width to permit the passing of trucks and workmen without crowding.

Proper illumination also should be considered in placing machines. The greatest possible amount of natural light should fall on the work, and yet not shine in the operator's eyes. The same principles should govern the arrangement of artificial lights.

## 4. WOOD-WORKING MACHINERY

Whenever practicable, wood-working machines should be selected for specific operations and guards should be provided suitable for such operations. Each machine then can be more effectively and permanently guarded.

**AUTOMATIC FEEDING** is much safer than hand feeding. It is recommended for every machine where the nature of the work permits.

**HOODS** connected with an exhaust system should be provided on wood-working machines in continuous or frequent use, to remove the sawdust, chips, or shavings. Otherwise these would clog the machine and reduce its efficiency, necessitate frequent cleaning with consequent danger of accidents, make the floors slippery, increase the fire hazard, and often irritate the eyes and injure the health of workmen. The exhaust hood, if made strong enough, may serve as a guard for the cutting tool on trimmers, stickers, molders, matchers, etc.

**SHARP TOOLS** are quite as necessary for safety as the provision of hood guards. They also increase efficiency.

**FLOORS** should be kept in good condition, with a smooth surface to prevent tripping, and kept free from accumulations of waste material, small sticks, blocks, shavings and sawdust. The standing space at each machine should be covered with anti-slip material. Metal plates with abrasive grit surfaces, rubber mats, or roofing paper, or a thick paint or glue applied periodically, with sand sprinkled over it while wet, may be used.

**CIRCULAR SAW GUARDS,** according to the National Safety Council, should: 1. Be of light weight, yet of substantial construction. 2. Be made preferably of aluminum (or of brass, fiber, or wood), so that accidental contact will not break the saw. 3. Permit a clear view of the saw blade at the point of operation, when in use. 4. Automatically and easily adjust themselves to different thicknesses of material. 5. Be rigidly supported to lessen vibration and danger of contact with saw. 6. Be so constructed that they can be swung out of the way when necessary, and return to proper position. 7. Be permanently attached to the machine. 8. The guard supports should not interfere with feeding of machine by operator. 9. Exposed part of saw below table should be completely protected, as by a suction hood for carrying off the sawdust.

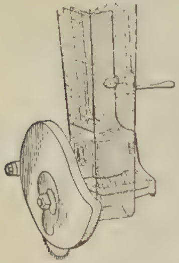

Fig. 6. Swing Saw Guard

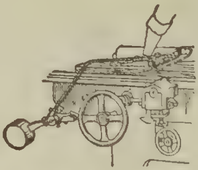

Fig. 7. Wood Planer Guard

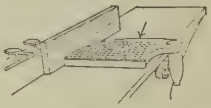

Fig. 8. Wood Planer Guard

**RIP SAWS** also should be equipped with a spreader or splitter to prevent the wood from binding on the saw blade, and to act as a guard for the back side of the saw blade.

**SWING SAWS** should have the counterweight securely fastened in place, and also secured to the ceiling by a safety chain. The travel should be confined within safe limits. The belt should be completely enclosed on the side toward operator for its entire length, and on the back side to at least 6 ft. above the floor. If a saw is located so that workmen can pass behind it, an enclosure should be built to prevent any one coming in contact with the saw blade. See Fig. 6.

**" RAILROAD " OR TRAVELING CUT-OFF SAWS** should have the hood supported from the saw carriage, thus keeping the hood always in position over the saw.

**SAFE RIM SPEED** of circular saws is about 15,000 ft. per min. or 4800 r.p.m. for a 12-in. saw, which may be increased by 25% in the case of special " high-speed " blades.

**BAND SAWS** should have upper and lower wheels completely enclosed, with the side of guard toward operator hinged or movable, for changing saw blades. The uprunning side of the blade should be completely guarded. The working side of the blade should be guarded above guide rolls or gage.

**JOINTERS AND PLANERS** (hand-fed) should be equipped with safety cylinder heads, and a guard as in Figs. 7 or 8. The part of the jointer head back of the guide should always be completely covered.

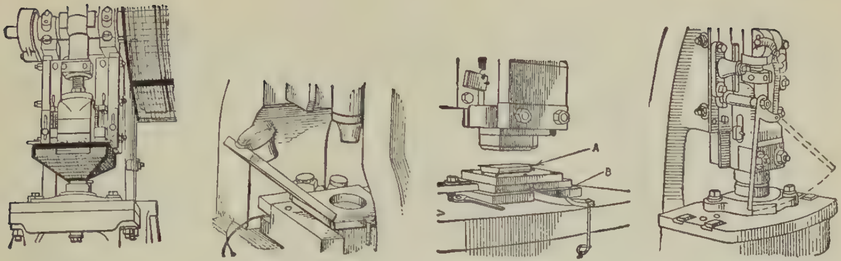

FIG. 9 FIG. 10 FIG. 11 FIG. 12
Methods of Guarding Punch Presses

**SHAPERS, MATCHERS, MOLDERS, STICKERS, ETC.,** should have cutting heads guarded by a cage or by the exhaust hood.

**ROLL FEEDS** should be guarded by a cover, or a bar in front of the intake, to prevent the operator's hands being drawn in.

Also see Safety Code for Wood-working Plants, Am. Stds. Assoc.

## 5. METAL-WORKING MACHINERY

**POWER PRESSES** (punch presses) can be made safe and also more efficient, by so arranging the press, dies, and feed that operator need never place his hand under the ram. Preferred methods are: *a*. Full-automatic feed (roll feed, plunger, chute, revolving or sliding die) with the ram guarded; basket-guard for hand-fed blanking work; see Fig. 9. *b*. Gravity feed for forming; see Fig. 10. *c*. Automatic or foot-operated kick-out; see Fig. 11. *d*. Pneumatic or other handpickers for placing and removing material. *e*. Redesign of dies to leave portion of material projecting so it may be grasped safely. If these methods cannot be used, provide a sweep guard, Fig. 12, attached to ram; a gate guard requiring removal of hand before the press can be tripped; or a two-hand operating device. In the last two cases, also provide non-repeat, and treadle-disconnecting attachments. In all cases provide a treadle guard, Fig. 13, to prevent accidental tripping, and also a friction clutch or tight-and-loose pulleys. Also see Safety Code for Power Presses, Am. Stds. Assoc.

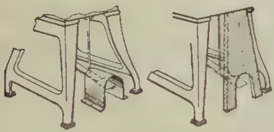

FIG. 13. Foot Treadle Guards

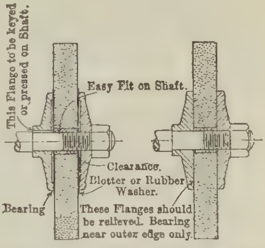
**LATHES.**—Gears should be enclosed. Safety dogs without projecting parts should be used. A guard around or in front of the chuck is advisable. Where the speed is changed frequently, a cone-pulley belt-shifter saves time and prevents accidents, and also permits the belt to be guarded.

**DRILL-PRESSES** should have belt shifter and belt guard the same as lathes.

**PLANERS** should have the openings in the bed covered. A railing or other guard should be provided if the table travels to within 18 in. of a wall or other fixed object.



This Flange to be keyed or pressed on Shaft.
Easy Fit on Shaft.
Clearance.
Blotter or Rubber Washer.
Bearing
These Flanges should be relieved. Bearing near outer edge only.

FIG. 14. Safety Flanges for Abrasive Wheels

## 6. MISCELLANEOUS MACHINERY AND EQUIPMENT

**ABRASIVE WHEELS** should have a hood, of sufficient strength to retain the fragments in case the wheel should burst, enclosing at least 270° of bench wheels, or at least the top 180° of swing frame grinders. See Safety Code for Abrasive Wheels, obtainable from most grinding wheel manufacturers or from Amer. Standards Association, 29 W. 39th St., New York. (See also p. 21–81.)

**ROLLS,** including calender or mixing rolls in paper, rubber, and other industries, also feed rolls, should be equipped with an enclosure, plate, or bar to keep the operator's fingers out of intake; or a feed table, for the same purpose; or a quick-stop device operated by a treadle, cord, or bar within easy reach of operator, and with a minimum of lost motion.

**TRAVELING CRANES** (electric overhead) should have a railed footwalk, 18 in. wide, along the bridge; fixed ladder or stair between cab and footwalk; fixed ladder or stair from floor of shop to cab; bumpers at each end of each rail; warning gong or other signal; enclosure or railing on all sides of cab; fenders on bridge wheels; over-hoist limit switch with dynamic braking.

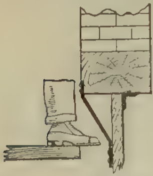


Fig. 15. Elevator Shaft Toe Guard

**ELEVATORS.**—Special safety features include: Bevel guards, Fig. 15, at least 60° from horizontal on all under-projections in shaft; gates or doors interlocking with the power control; substantial screen below overhead sheaves; proper car enclosure, including top; automatic catching device with speed governor; limit stops on machine and in shaft; device to stop machine if cable becomes slack; no-voltage and phase-reversal protection; floor lock for operating cable or shipper rope; non-slip floor in car at door, and on landings. See A.S.M.E. Elevator Code.

**STEAM BOILERS.**—Special safety features include: Location of safety valve and blow-off so as not to injure anyone in discharging; easy access to valves; two exits from boiler room; boiler valve lock, to protect men working in boiler; non-return valve; gage glass guard; furnace door lock. See A.S.M.E. Boiler Code and Section 6, Vol. 2 of this series.

**ENGINE FLY-WHEELS AND PITS** should be guarded as in Fig. 2 or 3, and Table 1. Keys and other projections should be covered. A speed governor should be provided, except for (*a*) reversing engines, and (*b*) engines direct-connected to a constant load. The following engine parts also need protection, according to the insurance rating schedule:

" Cranks, connecting rods, crossheads, tail rods, governor balls, gears, contact point of governor belt and pulley, exposed ends of engine shaft.

" **Cranks, Connecting-rod and Crosshead** shall be guarded by one of the following methods: 1. Engines with overhanging crank shall have a standard railing, Fig. 3, not less than 15 in. nor more than 20 in. from the moving part. 2. Center-crank engines shall have a guard in the form of a plate or wire mesh at each side of the crank at the main bearing. 3. When cranks or crossheads are housed in, the covering shall have an opening large enough to permit examination of the bearing, except in the case of engines with oil splash system, where such opening is not required.

" **Tail Rods** may be enclosed with sheet metal or wire fabric in such a way as to prevent danger of accidental contact with the moving end, or they may be protected by a standard railing placed between 15 in. and 20 in. away from the point of maximum travel.

" **Governor Belt and Pulley** so located that any person who in his regular duties may come in contact with them, shall be guarded by means of a solid metal plate, placed 1 to 2 in. from the pulley and at least 4 in. greater than the diameter of the pulley. It shall be rigidly supported and shall not interfere with inspection, oiling or operation of any part of the equipment.

" **Fly-ball Governors** within 7 ft. of floor or platform shall be protected by a substantial guard or basket of sheet metal, woven wire fabric, etc., so arranged as to prevent danger of accidental contact with the rotating ball.

" If any engine parts are guarded by railings, the railings shall be of standard construction, and covered with wire fabric, sheet metal or other suitable material at all points within 15 in. of moving parts. The clearance between the plane of the railing and the moving parts which it protects shall not exceed 20 in."

**PORTABLE LADDERS** should be equipped with anti-slip bases of a type suited to the floor; for rough wood floors, metal points or lead-coated bases; for concrete floors, lead or carborundum. For some floors, such as iron or wet concrete, it is almost impossible to find a ladder shoe which will not sometimes slip and the only safe practice is to station an attendant at the foot or to lash the ladder at top or bottom or both.

**Stationary Ladders** should have proper clearance on all sides—8 to 12 in. in the back, 24 to 36 in. in front, 15 in. on each side of the center line of the ladder. For vertical ladders, especially if of considerable height, an enclosure or backrest is desirable.

## 7. ELECTRICAL HAZARDS

The construction of high voltage generating equipment and transmission lines is discussed under Electrical Engineering, Section 15, Vol. 2 of this series. See also Pender, Electrical Engineers' Handbook, Vol. 4 of this series. All other phases of electrical safety are covered in detail in the National Electrical Safety Code (U. S. Bureau of Standards, Washington).

**UTILIZATION HAZARDS** are chiefly low-voltage, except the step-down transformer, which should be carefully isolated from all but qualified persons. Plant equipment of 550 volts is admittedly hazardous, and 220 or even 110 volts may kill or injure a person in poor health, standing on or touching a direct ground. Present practice, therefore, favors the enclosure of all switches. Portable lights should have heavily insulated cord; if the user is on a " ground " the socket should be keyless, with an insulating enclosure and handle. Motors, generators, switchboards, transformers, etc., should be enclosed or protected if within 8 ft. of the floor or working platform. Circuits of from 25 to 150 volts to ground should be permanently grounded, except two-wire direct-current systems and circuits exposed to leakage or induction from higher voltages. Motor, generator, transformer, and switch frames, and cases, should be grounded if operating at over 150 volts to ground or if exposed to inflammable gas or explosives, or if within reach of other exposed grounded surfaces. Working space next to live parts carrying over 150 volts to ground should be at least 30 in.; not over 150 volts, 18 in.; space between live parts (over 150 volts) on one side and live or grounded parts on other side, 48 in.; not over 150 volts, 30 in.

## 8. INDUSTRIAL BUILDINGS AND PLANTS

Forethought in the arrangement of buildings and equipment will avoid hazards which later are difficult or impossible to remove. The most common hazards to be considered are:

**CLEARANCE** between railroad track and building—8 1/2 ft. from center of track; between end of crane bridge and wall or column; below present or future overhead pipes, ducts, shafting, etc.; between stairs and floor above.

**ACCESSIBILITY** of valves, switches, oil cups, lamps, etc., should be obtained either by location or by providing runways and stairs or fixed ladders.

**CROSSINGS** of railroad, automobile, hand-truck and pedestrian traffic can often be avoided by careful planning.

**LIGHTING** is necessary for safety as well as efficiency. See Illumination, p. 26–12, and also the specifications of the Illuminating Engineering Society (New York).

**EXITS.**—Provide at least two exits from every point. Preferred types are stairs enclosed with fire-resisting walls and fire-doors and " horizontal exits," *i.e.*, doors through fire walls, or bridges or balconies to other buildings or sections. Outside fire escapes are less safe; if used at all, they should be not steeper than 45°, substantially constructed, well railed, extended to ground, and protected by wire glass windows. See specifications of National Fire Protection Association (Boston).

**STAIR RAILS** 36 in. from center of tread should be provided: On all open sides of stairs; on one side of enclosed stairway 4 ft. wide or less; on both sides of enclosed stairway over 4 ft. wide between walls; on both sides and in center of stairway over 8 ft. wide between walls. (See Figs. 3 and 4.)

**FLOORS** should be of material which, under the usage to which they are exposed, will not splinter nor become slippery, loose, or uneven. Cast-iron or steel door sills, steps, etc., become dangerously slippery unless an anti-slip element is provided.

**FLOOR OPENINGS** should be enclosed or guarded with standard railings (Figs. 3 and 4) or be equally protected with fixed safety covers with bows and rods. All openings through which articles might drop and injure people below should be guarded with standard toe boards. See Figs. 3 and 4. See also Safety Code for Floor and Wall Openings, Am. Stds. Assoc.

## 9. EYE PROTECTION AND SAFE CLOTHING

**THE HEAD AND EYE PROTECTION** Code of the U. S. Bureau of Standards classifies eye hazards as follows (with example of each class):

*a*. Large flying objects—*e.g.*, chipping; *b*. Dust and small flying particles—grinding; *c*. Dust and wind—automobile driving; *d*. Splashing metal—babbitting; *e*. Gases, fumes and liquids—acid handling; *f*. Excessive dust and flying particles—sand-blasting; *g*. Reflected light or glare—snow-covered ground; *h*. Injurious radiant energy of moderate intensity—oxy-acetylene welding; *i*. Injurious radiant energy of high intensity—electric welding. The code contains specifications for protectors for each type of hazard. The lenses of chipping goggles must, when placed horizontal, withstand 10 blows of a 16-gram steel ball falling 54 cm., or one blow from a height of 1 meter. Goggles used only for grinding, may be lighter. Those used for protection against dust or acids must fit the face closely, and in the latter case also must withstand corrosion. Lenses used in welding and similar operations must comply with certain specifications limiting the transmission of invisible as well as visible rays. For all types, strong and durable frames are specified.

Helmets are worn in some cases, instead of goggles. For exposure to poisonous gases, helmets or masks contain a filter like the army gas-mask, or an oxygen supply, or are connected with a hose leading to the outer air.

**Underwriters' Laboratories Label** is placed only on goggles or helmets complying with standard requirements.

**To Persuade Workmen** to wear goggles, provide a pair for each man, fitted to his face and to the spacing of his eyes and (if he regularly wears glasses) ground to his optical prescription. Education and discipline must do the rest.

**LEGGINGS** should be made of material which will prevent the molten metal or corrosive substances that are being handled from coming into contact with the leg of the wearer. They should make a tight enclosure when being worn. Leggings should be so fastened that they can be put on or taken off quickly. They always should be kept in good repair, otherwise a false sense of security may be established which will lead to the taking of unnecessary risks.

**PROTECTIVE SHOES** should be made of material which will not be easily affected by the substances being handled, should closely fit the contour of the foot and ankle, be so designed that liquid or molten material cannot enter the shoe; be easily and quickly removed from the foot and kept in good repair. Metal soles sometimes are used for protection against stepping on sharp objects; and rubber soles for electrical work.

**GLOVES** and arm protectors of proper type are a safeguard against cuts and scratches, in handling material; they should fit loosely so the hand may be withdrawn if the glove becomes caught. In machine work gloves often are a hazard as they may be caught and pull in the hand and arm; if worn at all, they should be hard finished, fit very loosely, and if possible be without fingers. Rubber gloves for electricians must be tested frequently, as a pin prick or worn place destroys their value.

**ALL CLOTHING** worn near machinery or fires should be free from loose ends. Loose or ragged sleeves or other garments, flowing ties or ribbons, jewelry including rings, and long hair unless confined by a cap are dangerous for both men and women machine operators. Aprons, if required, should be lightly secured to the body. One-piece overalls are favored.

## 10. FIRST AID

The immediate and proper care of injuries, both large and small, minimizes the resulting loss of time and often prevents permanent crippling or serious infection. The equipment and operation of a medical and surgical department such as is maintained by many large industries is beyond the scope of this book. First-aid treatment by fellow-employees who have received certain elementary training, is valuable wherever medical attention is not immediately available. Such treatment must be recognized as temporary only, and the injury should in every case be examined and re-dressed as soon as possible by a physician or graduate nurse, acting under medical supervision, either within or outside of the plant.

**INFECTION** of slight injuries causes many cases of prolonged disability, amputation, or death. Workmen should be strictly required to report all injuries, however slight, and have them dressed. First-aid stations at convenient points, with competent attendants, make it possible to enforce such a rule.

**FIRST-AID OUTFITS AND METHODS.**—Standard outfits may be obtained from medical supply dealers. An outfit for general use may contain iodine, aromatic spirits of ammonia, ampoules, toothpicks (as applicators), absorbent cotton, adhesive tape, scissors, roll and triangular bandages, sterile gauze, ointment, and instruction book. A smaller kit for minor injuries may include only iodine, applicators, and finger bandages. First-aid stations in mines and at other points, where a well-trained first-aid team is available, require splints, tourniquets, and other additional equipment. For further information on equipment, methods of treatment, and methods of training, consult the American Red Cross (Washington, D. C.) or U. S. Bureau of Mines (Washington, D. C.).

## 11. SUPERVISION AND EDUCATION

The accomplishments of those industrial concerns which have reduced their accidents by from 50 to 90%, with large money savings, have been brought about not alone by guarding obvious points of danger as described above but by a combination of: 1. Mechanical guarding; 2. Re-design of machinery, and revision of operating methods, which were inherently dangerous; 3. Strict supervision by executives, from manager to foremen, to enforce the use of safe methods of work; 4. Training of workmen, both in general habits of carefulness and in the safe conduct of their particular jobs.

These things are most easily accomplished through an organized effort, or continuous campaign, in which the ten necessary steps are outlined by the National Safety Council as follows: *a.* Secure co-operation of manager; *b.* Secure co-operation of superintendent; *c.* Appoint a safety engineer; *d.* Appoint a central safety committee; *e.* Secure co-operation of foreman and sub-foreman; *f.* Organize foremen's safety meetings; *g.* Appoint foremen's inspection committee; *h.* Hold safety mass meeting for all employees; *i.* Appoint workmen's safety committees; *j.* Start use of safety bulletin boards.

**THE MANAGER AND THE SUPERINTENDENT** must actively support the safety campaign and must be willing to authorize necessary expenditures.

**THE SAFETY ENGINEER OR INSPECTOR** either (1) is held directly responsible for all safety work, or (2) acts as expert adviser to the operating executives if they are held responsible. In a small plant he may give part time to other work. His duties include the following:

*a.* Check up unsafe practices, insanitary conditions, the use and need of safeguards, etc.; *b.* Keep in touch with foremen and secure their co-operation by serving them; *c.* Recommend methods of safeguarding and follow-up installations; *d.* Check all specifications and drawings for new equipment or repairs to see that provision is made for safety; *e.* Supervise bulletin board service; *f.* Supervise safety educational activities; *g.* Arrange programs for safety meetings; *h.* Investigate all serious accidents and near accidents; *i.* Keep records and prepare reports on accident experience.

**THE CENTRAL SAFETY COMMITTEE** composed of the superintendent (chairman), safety engineer (secretary), and such men as chief engineer, master mechanic, employment manager, purchasing agent, and department superintendents should head the safety organization and: *a.* Pass on controversial matters; *b.* Establish standards for safeguards; *c.* Review reports and recommendations of safety engineer, foremen, and workmen; *d.* Formulate safety rules; *e.* Outline educational methods and direct safety campaigns; *f.* Study accident experience tabulated by safety engineer.

**THE FOREMEN** determine the success or failure of safety work. They should: *a.* Instruct their men, especially new men; *b.* Enforce safety rules with wise discipline; *c.* See that tools and machines are kept in proper repair and adjustment; *d.* Inspect their departments and render weekly reports; *e.* Investigate accidents and near accidents and recommend methods of prevention; *f.* Keep closely in touch with and encourage the workmen's safety committees. Monthly foremen's safety meetings should take up inspection and progress reports, recommendations, and accident experience. In large plants, inspection by a foremen's committee will standardize practices in the different departments.

**WORKMEN'S SAFETY COMMITTEES** keep up the interest of workmen. They should: *a.* Make regular inspections to discover unsafe conditions and practices and submit to the foreman a written report of findings; *b.* Instruct and warn fellow workmen regarding dangerous practice; *c.* Investigate all serious accidents and near accidents and submit reports and recommendations.

**SAFETY BULLETIN BOARDS** containing pictures and stories which drive home what the workman can do to protect himself, are recognized as one of the most effective means of reaching the men. Bulletin boards should be placed at convenient points in each department. The secret of a live bulletin board is constant change. In addition to the National Safety Council safety bulletins, home-made bulletins should be used covering accidents or near accidents which have actually occurred in the plant, together with interesting exhibits, such as goggles which prevented eye injuries.

## 12. ORGANIZATIONS

The following is a list of organizations that concern themselves principally with the development of safe practices in industry, or which regard safe practice as an important, although not a major, activity. It is advisable to consult with one or more of these organizations in relation to any special construction or operation that is not covered by an existing safety code.

**National Safety Council** (20 North Wacker Drive, Chicago) is an association of manufacturing and other industrial concerns, insurance companies, engineers, public officials, and others; publishes *National Safety News* (magazine), workmen's bulletins or posters, "Safe Practices" pamphlets on a variety of special subjects; holds annual congress, maintains information bureau; fosters local safety councils; also publications and activities relating to public safety and industrial health.

**Safety Institute of America** (New York) publishes *Safety* (magazine), maintains a safety museum and special service to members.

**American Society of Safety Engineers** (Engineering Section of National Safety Council) is composed of individuals in safety work.

**American Standards Association** (New York) has general supervision of safety code work.

Formulation of specific codes, and other safety investigations have been undertaken by the organizations already named and by the U. S. Bureau of Standards (Washington, D. C.); U. S. Bureau of Mines (Washington, D. C.); Natl. Bureau of Casualty and Surety Underwriters (New York), maintained by stock insurance companies; National Assoc. of Mutual Casualty Companies (New York); American Society of Mechanical Engineers. Underwriters' Laboratories (Chicago) tests, inspects, and labels safety and fire-protection equipment conforming to its standards. Numerous trade associations have safety departments or safety committees.

## LOGARITHMS

**Logarithms** (abbreviation *log*).—The log of a number is the exponent of the power to which it is necessary to raise a fixed number to produce the given number. The fixed number is called the *base*. Thus if the base is 10, the log of 1000 is 3, for $10^3 = 1000$. There are two systems of logs in general use, the *common*, in which the base is 10, and the Napierian, or *hyperbolic*, in which the base is 2.718281828. . . . The Napierian base is commonly denoted by $e$, as in the equation $e^y = x$, in which $y$ is the Napierian log of $x$. The abbreviation $\log_e$ is commonly used to denote the Napierian log.

In any system of logs, the log of 1 is 0; the log of the base, taken in that system, is 1. In any system the base of which is greater than 1, the logs of all numbers greater than 1 are positive and the logs of all numbers less than 1 are negative.

The modulus of any system is equal to the reciprocal of the Napierian log of the base of that system. The modulus of the Napierian system is 1, that of the common system is 0.4342945. The log of a number in any system equals the modulus of that system × Napierian log of the number. The *hyperbolic* or *Napierian* log of any number equals the common log × 2.3025851.

Every log consists of two parts, an integral part called the *characteristic*, or index, and the decimal part, or *mantissa*. The mantissa only is given in the usual tables of common logs, with the decimal point omitted. The characteristic is one less than the number of figures to the left of the decimal point in the number whose log is to be found. The characteristic of numbers from 1 to 9.99+ is 0, from 10 to 99.99+ is 1, from 100 to 999+ is 2, from 0.1 to 0.99+ is −1, from 0.01 to 0.099+ is −2, etc. Thus,

log of 2000 is 3.30103; log of 0.2 is −1.30103, or 9.30103 − 10
" " 200 " 2.30103; " " 0.02 " −2.30103, " 8.30103 − 10
" " 20 " 1.30103; " " 0.002 " −3.30103, " 7.30103 − 10
" " 2 " 0.30103; " " 0.0002 " −4.30103, " 6.30103 − 10

The minus sign is frequently written above the characteristic thus: log 0.002 = $\bar{3}.30103$. The characteristic only is negative, the decimal part, or mantissa, being always positive.

When a log consists of a negative index and a positive mantissa, it is usual to write the negative sign over the index, or to add 10 to the index, and indicate the subtraction of 10 from the resulting logarithm. Thus log 0.2 = $\bar{1}.30103$, may be written 9.30103 − 10. The difference between a logarithm and 10 is its *arithmetical complement* or **cologarithm.**

In tables of logarithmic sines, etc., the −10 is generally omitted, as being understood.

RULES FOR USE OF THE TABLE OF COMMON LOGARITHMS.—**To Find the Log of a Decimal Fraction or of a Whole Number and a Decimal.**—First find the log of the quantity as if there were no decimal point, then prefix the index according to rule; the index is one less than the number of figures to the left of the decimal point.

EXAMPLE. log of 3.14159. log of 3.141 = 0.497068. Diff. = 138.
From proportional parts 5 = 690
" " " 09 = 1242
log 3.14159 0.4971494

If the number is a decimal less than unity, the index is negative and is one more than the number of zeros to the right of the decimal point. Log of 0.0682 = $\bar{2}.833784$ = 8.833784 − 10.

**To Find the Number Corresponding to a Given Log.**—Find in the table the log nearest to the decimal part of the given log and take the first four digits of the required number from the column N and the top of the column containing the log which is the next less than the given log. To find the 5th and 6th digits subtract the log in the table from the given log, and multiply the difference by 100. and divide by the figure in the Diff. column opposite the log; annex the quotient to the four digits already found, and place the decimal point according to the rule; the number of figures to the left of the decimal point is one greater than the index. The number corresponding to a log is called the anti-logarithm.

Find the anti-log of.............................. 0.497150
Next lowest log in table corresponds to 3141........ $\underline{0.497068}$ Diff. = 82.
Tabular diff. = 138; $82 \div 138 = 0.59+$

The index being 0, the number is therefore 3.14159+.

**Multiplication by Means of Logarithms.**—Add together the logs of the two numbers to be multiplied. The sum is the log of the product.

*a*. Where both factors are greater than unity.

EXAMPLE. $31 \times 1274 = 39{,}494$.

*Solution.* $\log 31 + \log 1274 = 1.491362 + 3.105169 = 4.596531 = \log 39{,}494$.

*b*. Where one or more factors are less than unity, the logs with a negative characteristic can be handled most conveniently by adding and subtracting 10.

EXAMPLE. $.000028961 \times .084507 = .0000024474$.

*Solution.* $\log .000028961 + \log .084507 = \bar{5}.461814 + \bar{2}.926893$.
$= (5.461814 - 10) + (8.926893 - 10) = 14.388707 - 20 = \bar{6}.388707$
$= \log .0000024474$.

**Division by Means of Logarithms.**—Subtract the log of the divisor from the log of the dividend. The remainder is the log of the quotient.

*a*. When the divisor is smaller than the dividend.

EXAMPLE. $2987 \div 63 = 47.41284$.

*Solution.* $\log 2987 - \log 63 = 3.475235 - 1.799341 = 1.675894 = \log 47.41284$.

*b*. When the divisor is larger than the dividend, add and subtract as many tens as may be necessary to the log of the dividend and proceed as before.

EXAMPLE. $.000672 \div 263 = .00000255513$.

*Solution.* $\log .000672 - \log 263 = \bar{4}.827369 - 2.419956$
$= 6.827369 - 2.419956 - 10 = \bar{6}.407413 = \log .00000255513$.

*c*. The log of a fraction is obtained by subtracting the log of the denominator from the log of the numerator. Thus,

$$\log \frac{a}{b} = \log a - \log b.$$

**To Raise a Number to Any Given Power.**—Multiply the log of the number by the exponent of the number, and find the number whose log is the product.

*a*. Where the exponent consists of one figure.

EXAMPLE. $16.2^3 = 4251.528$.

*Solution.* $3 \times \log 16.2 = 3 \times 1.209515 = 3.628545 = \log 4251.528$.

*b*. Where the exponent consists of two or more figures, it is best to multiply the characteristic and mantissa separately.

EXAMPLE. $.005624^{.37} = .147067$.

*Solution.* $.37 \times \log .005624 = .37 \times \bar{3}.750045 = .37 \times (-3) + .37 \times .750045$
$= -1.11 + .277517 = \bar{1}.167517 = \log .147067$.

*c*. Where the number is a fraction, first find the log of the fraction and then multiply it by the exponent.

EXAMPLE. $\left(\frac{276}{.032}\right)^{.72} = 681.9396$.

*Solution.* $.72 (\log 276 - \log .032) = .72\{2.440909 - (8.505150 - 10)\}$
$= .72 \times 3.935759 = 2.833746 = \log 681.9396$.

**To Extract Any Root of a Number.**—Divide the log of the number by the index of the root, and find the number whose log is the quotient.

To extract the root of a decimal: *a*. When the root index is positive and evenly divisible into the negative characteristic of the log of the number, the division may be performed with the negative characteristic written in its usual place.

EXAMPLE. $\sqrt[4]{.0006954} = .16239$.

*Solution.* $\log .0006954 \div 4 = \bar{4}.842235 \div 4 = \bar{1}.210559 = \log .16239$.

*b*. When the root index is positive and not even divisible into the negative characteristic, add to the log of the number, and indicate the subtraction from it, the smallest integral multiple of the root which will eliminate the negative characteristic. Divide the result by the root index and ascertain the number whose log corresponds to the quotient.

EXAMPLE. $\sqrt[3.1]{.00002785} = .03393$.

*Solution.* $\log .00002785 = \bar{5}.444825$; $\bar{5}.444825 \div 3.1 = \{(2 \times 3.1) + \bar{5}.444825 - 2 \times 3.1\} \div 3.1$
$= \{1.644825 - 6.2\} \div 3.1 = \bar{2}.530589 = \log .03393$.

*c*. When the root index is negative, determine the excess of the negative characteristic over the positive mantissa. Divide the result by the root index and ascertain the number whose log corresponds to the quotient.

EXAMPLE. $\sqrt[-4]{.000003976} = 22.394$.

*Solution.* $\log .000003976 = \bar{6}.599446 = .599446 - 6 = -5.400554$;
$-5.400554 \div (-4) = 1.350138 = \log 22.394$.

**Solution of Exponential Equations.**—In an exponential equation, the unknown quantity is the exponent; thus $a^x = b$. This may be transformed to $\log a^x = \log b$, or $x \log a = \log b$, whence $x = \log b \div \log a$.

*a.* When the base is greater than unity, put the equation in the form $x = \log b \div \log a$. Then $\log x = \log (\log b) - \log (\log a)$.

EXAMPLE. $32.6^x = 14.632$.

*Solution.* $\log x = \log (\log 14.632) - \log (\log 32.6) = \log 1.165303 - \log 1.513218$
$= .066439 - .179901 = \bar{1}.886538;\ x = .77008.$

*b.* When both the known quantities are decimal, put the equation in the form $x = \log b \div \log a$. Subtract the positive mantissa from the negative characteristic in both divisor and dividend, obtaining negative remainders. Change the signs of divisor and dividend and proceed as in Case *a*.

EXAMPLE. $.0729^x = .2693$.

*Solution.* $x = \log .2693 \div \log .0729 = \bar{1}.430236 \div \bar{2}.862728$
$= (-.569764) \div (-1.137272) = .569764 \div 1.137272;$
$\log x = \log .569764 - \log 1.137272 = \bar{1}.755695 - .055864 = \bar{1}.699831$
$x = .50099.$

*c.* When only one of the known quantities is a decimal, put the equation in the form $x = \dfrac{\log b}{\log a}$. Subtract the positive mantissa from the negative characteristic of the numerator or denominator as the case may be, and rewrite the fraction with the remainder so obtained as the new numerator or denominator. Make both numerator and denominator positive, but write a minus sign in front of the fraction, to signify that the result will be a negative quantity. Solve the fraction by logarithms and write a minus sign in front of the result.

EXAMPLE. $.726^x = 802.7$.

$$\text{Solution.}\quad x = \frac{\log 802.7}{\log .726} = \frac{2.904553}{\bar{1}.860937} = \frac{2.904553}{-.139063} = -\frac{2.904553}{.139063}.$$

$\log x = -(\log 2.904553 - \log .139063) = (.463079 - \bar{1}.143211) = -(1.319868)$
$x = -20.8867$

*d.* When the exponent is negative and one of the known quantities is less than unity, put the equation in the form $(-x) = \dfrac{\log b}{\log a}$. Subtract the positive mantissa from the negative characteristic, as in Case *c*, and multiply both sides of the resulting equation by $(-1)$. Find the value of $x$ as in Case *c*.

EXAMPLE. $10.78^{-x} = .09431$.

$$\text{Solution.}\quad x = \frac{\log .09431}{\log 10.78} = \frac{\bar{2}.974558}{1.032619};\ x = \frac{1.025442}{1.032619}.$$

$\log x = .010911 - .013940 = \bar{1}.996971.\quad x = .99305.$

**Table 1. Logarithms of Numbers from 1 to 100**

| N | Log | N | Log | N | Log | N | Log | N | Log |
|---|---|---|---|---|---|---|---|---|---|
| 1 | 0.000000 | 21 | 1.322219 | 41 | 1.612784 | 61 | 1.785330 | 81 | 1.908485 |

## Table 3.—Natural (Napierian or Hyperbolic) Logarithms of Numbers

Table gives natural logarithms of numbers from 1.0 to 9.99 directly. To find logarithms of numbers outside that range add or subtract natural logarithm of the powers of 10 as follows:

$\log_e 10 = 2.302585$ $\log_e 10^4 = 9.210340$ $\log_e 10^7 = 16.118096$
$\log_e 10^2 = 4.605170$ $\log_e 10^5 = 11.512925$ $\log_e 10^8 = 18.420681$
$\log_e 10^3 = 6.907755$ $\log_e 10^6 = 13.815511$ $\log_e 10^9 = 20.703266$

**Example.**—$\log_e 679. = \log_e 6.79 + \log_e 10^2 = 1.9155 + 4.6052 = 6.5207$
$\log_e .0679 = \log_e 6.79 - \log_e 10^2 = 1.9155 - 4.6052 = -2.6897$

The common logarithm is the natural logarithm multiplied by the modulus of $\log_{10}$: $\log_{10} N = 0.434294 \log_e N$.

## CIRCULAR ARCS, CHORDS, SEGMENTS AND SECTORS

**Notation.**—$A$ = central angle, degrees; $C$ = chord of arc; $c$ = chord of $1/2$ arc; $D$ = diameter; $G$ = area of segment; $H$ = rise of arc or height of segment; $L$ = length of arc; $R$ = radius; $S$ = area of sector.

$$L \text{ (exact)} = 2\pi RN/360 = 0.017453RN$$

$$L \text{ (approx.)} = (8c - C)/3 = \{(2c \times 10H)/(60D - 27A)\} + 2c$$
$$= \{(\sqrt{C^2 + 4H^2} \times 10H^2)/(15C^2 + 33H^2)\} + 2c$$

$$C = 2\sqrt{c^2 - H^2} = \sqrt{D^2 - (D - 2H)^2} = (8c - 3L) = 2\sqrt{R^2 - (R - H)^2} = 2\sqrt{(D - H) \times H}$$

$$C/2 = \sqrt{H \times (D - H)}; \quad c = 1/2\sqrt{C^2 - 4H^2} = \sqrt{D \times H} = (3L + C)/8$$

$$D = c^2/H = (1/4\,C^2 + H^2)/H$$

$$H = c^2/D = 1/2\,(D - \sqrt{D^2 - C^2}) \text{ when } H < R; = 1/2\,(D + \sqrt{D^2 - C^2}) = \sqrt{c^2 - 1/4\,C^2} \text{ when } H > R$$

$$G = S - 1/2\,C\sqrt{R^2 - 1/4\,C^2} \text{ when } G < \text{semi-circle}; = S + 1/2\,C\sqrt{R^2 - 1/4\,C^2} \text{ when } S > \text{semi-circle}$$
$$= S - (C/2)(R - H) = 1/2\,\{(L - C)(D/2) + CH\}$$

$$S = 1/2\,LR = \pi AR^2/360 = (\pi R^2/360) \times 2[\sin^{-1}\{(C/2)/R\}]; \quad R = (C^2+4H^2)/8H$$

* Area of segment of any radius = factor *G* × square of radius

## Table 6.—Areas of Segments of a Circle

Area = $F \times D^2$ where segment < semicircle; $= \frac{1}{4}\pi D^2 -$ (area of segment of rise $h$). $H$ = rise or height of segment; $D$ = diam. of circle; $F$ = factor corresponding to $H/D$. $h = (D - H)$

| H/D | F | H/D | F | H/D | F | H/D | F | H/D | F | H/D | F |

| **3900** | 7052 | 7070 | 7088 | 7106 | 7124 | 7142 | 7160 | 7178 | 7196 | 7214 |

EXAMPLES: 1347° C. = 1340° C. + 7° C. = 2444° F. + 12.6° F. = 2456.6° F.
−194° C. = − 190° C. + (− 4° C.) = − 310° F. + (− 7.2° F.) = − 317.2° F.
1852° F. = 1850° F. + 2° F. = 1010° C. + 1.11° C. = 1011.11° C.
−226° F. = − 220° F. + (− 6° F.) = − 134.44° C. + (− 3.33° C.) = − 137.77° C.

In the Fahrenheit thermometer the freezing-point of water is taken at 32°, and the boiling-point of water at mean atmospheric pressure at the sea-level, 14.7 lb. per sq. in., is taken at 212°, the distance between these two points being divided into 180°. In the Centigrade and Réaumur thermometers the freezing-point is taken at 0°. The boiling-point is 100° in the Centigrade scale, and 80° in the Réaumur.

| | | |
|---|---|---|
| 1 Fahrenheit degree | = $^{5}/_{9}$ deg. Centigrade | = $^{4}/_{9}$ deg. Réaumur. |
| 1 Centigrade degree | = $^{9}/_{5}$ deg. Fahrenheit | = $^{4}/_{5}$ deg. Réaumur. |
| 1 Réaumur degree | = $^{9}/_{4}$ deg. Fahrenheit | = $^{5}/_{4}$ deg. Centigrade. |
| Temperature Fahrenheit | = $^{9}/_{5}$ × temp. C. + 32° | = $^{9}/_{4}$ temp. R. + 32°. |
| Temperature Centigrade | = $^{5}/_{9}$ (temp. F. −32°) | = $^{5}/_{4}$ temp. R. |
| Temperature Réaumur | = $^{4}/_{5}$ temp. C. | = $^{4}/_{9}$ (temp. F. −32°) |

## MEASURES AND WEIGHTS COMMONLY USED IN THE UNITED STATES AND GREAT BRITAIN

### Abbreviations

bbl. = barrel
bu. = bushel
chn. = chain
circm. = circumference
cir. in. = circular inch
cir. mil. = circular mil
cwt. = hundred weight
deg. = degree
drm. = drachm (dram)
dwt. = pennyweight
fath. = fathom
ft. = foot
fl. drm. = fluid drachm
fl. oz. = fluid ounce
furl. = furlong
gal. = gallon (U.S.)
grn. = grain
hghd. = hogshead
hr. = hour
Imp. = Imperial (bu., gal.)
in. = inch
lea = league
m. pace = military pace
min. = minute
naut. mi. = nautical mile
pnch = puncheon
quad. = quadrant
quin. = quintal
qr. = quarter
qt. = quart
scr. = scruple
sec. = second
sq. = square (in., ft., etc.)
stat. mi. = statute mile
trce. = tierce
yd. = yard

### Table 16.— Measures of Length

**Long Measure**

12 in. = 1 ft.
3 ft. = 1 yd.
5 1/2 yd. = 16 1/2 ft. = 1 rod, pole or perch
40 poles = 220 yd. = 1 furl.
8 furl. = 1760 yd. = 5280 ft. = 1 mile
4 in. = 1 hand
9 in. = 1 span
2 1/2 ft. = 1 m. pace.

**Land, Surveyors, or Gunter's Measure**

7.92 in. = 1 link
100 links = 66 ft. = 4 rods = 1 chn.
10 chn. = 220 yd. = 1 furl.
8 furl. = 80 chn. = 1 mile.

**Nautical Measure**

6080.26 ft. = 1.15156 stat. mi. = 1 naut. mi.
3 naut. mi. = 1 lea.
60 naut. mi. = 1 deg. (at equator)
6 ft. = 1 fath.
120 fath. = 1 cable
1 naut. mi. per hr. = 1 knot.

### Table 17.— Measures of Area

**Square Measure**

144 sq. in. = 183.35 cir. in. = 1 sq. ft.
9 sq. ft. = 1 sq. yd.
30 1/4 sq. yd. = 272 1/4 sq. ft. = 1 sq. rod
160 sq. rods = 10 chn. }
4840 sq. yd. = 43560 sq. ft. } = 1 acre
640 acres = 27,878,400 sq. ft. = 1 sq. mile
1 acre = $(208.71\ \text{ft.})^2$
1 cir. in. = { area of circle 1 in. diam. = 0.7854 sq. in.
1 cir. mil = { area of circle 0.001 in. diam. = $0.0_5 7854$ sq. in.
1,000,000 cir. mil = 1 cir. in.

**Board Measure**

144 cu. in. = 12 × 12 × 1 in. = 1 board ft.

The above definition of a board foot applies to rough green lumber. American practice uses a yard standard of 29/32 in. thick and an industrial standard of 7/8 in. thick for rough dry lumber; for dressed lumber the corresponding thicknesses are 25/32 in. and 13/16 in. For example, a rough dry piece 12 × 12 × 29/32 in. contains 1 board ft. Board ft. in round timber = $(1/4\, c \times d \times l)/144$. $c$ = mean circm., $d$ = diam., $l$ = length, all in ft.

### Table 18.—Measures of Weight

(The grain is the same in all systems.)

**Avoirdupois Weight**

16 drm. = 437.5 grn. = 1 oz.
16 oz. = 7000 grn. = 1 lb.
14 lb. = 1 stone
28 lb. = 2 stone = 1 qr.
100 lb. = 1 quin.
4 qr. = 112 lb. = 1 cwt.
20 cwt. = 2240 lb. = 1 long ton
2000 lb. = 1 short ton.

**Troy Weight (for gold and silver)**

24 grn. = 1 dwt.
20 dwt. = 480 grn. = 1 oz.
12 oz. = 5760 grn. = 1 lb.
1 Assay ton = 29,167 milligrams
= { Troy oz. per 2000 lb. ton avoirdupois

**Carat Weight (for precious stones)**

1 carat = 3.086 grn. = 0.200 gram

**Apothecaries' Weight**

20 grn. = 1 scr. ℈
3 scr. = 60 grn. = 1 drm. ʒ
8 drm. = 480 grn. = 1 oz. ℥
12 oz. = 5760 grn. = 1 lb.

### Table 19.—Measures of Volume

**Cubic Measure**

1728 cu. in. = 1 cu. ft.
27 cu. ft. = 1 cu. yd.
1 cord of wood = { 4 × 4 × 8 ft. = 128 cu. ft.
1 perch masonry = { 16 1/2 × 1 1/2 × 1 ft. = 23 3/4 cu. ft.

**Liquid Measure**

4 gills = 1 pint
2 pints = 1 qt.
4 qt. = 231 cu. in. = 8.3356 lb. $H_2O$
= 1 U. S. gal.
= 0.8327 Imp. gal.
1 Imp. gal. = 277.420 cu. in.
= 10 lb. $H_2O$
1.20094 U. S. gal. = 1 Imp. gal.
7.4805 U. S. gal. = 1 cu. ft.

**Old Liquid Measure**

31 1/2 gal. = 1 bbl.
42 gal. = 1 trce.
2 bbl. = 63 gal. = 1 hghd.
84 gal. = 2 trce. = 1 pchn.
2 hghd. = 126 gal. = 1 pipe or butt
2 pipes = 3 pchn. = 1 tun.

**Apothecaries' Fluid Measure**

60 minims = 1 fl. drm.
8 drm. = 1 fl. oz.
1 fl. oz. = 1/128 U. S. gal. = 1.8047 cu. in. = 456.3 grn. $H_2O$ at 39° F.
16 fl. oz. = 1 pint
1 fl. oz. (British) = 1.732 cu. in.
= 437.5 grn. $H_2O$ at 62° F.

**Dry Measure**

2 pints = 1 qt.
8 qts. = 1 peck
4 pecks = 2150.42 cu. in.
= 1 bu. (struck)
1 1/4 bu. (struck) = 1 bu. (heaped)
105 qts. (struck) = 7056 cu. in. = 1 bbl.
8 Imp. gal. = 2218.192 cu. in.
= 1 Imp. bu.
8 Imp. bu. = 1 qr.

**Shipping Measure**

100 cu. ft. = 1 Register ton *
40 cu. ft. = 31.143 U. S. bu.
= 1 shipping ton (U. S.) †
42 cu. ft. = 32.719 Imp. bu.
= 1 shipping ton (British) †

* For measurement of entire internal capacity. † For measurement of cargo.

**Miner's Inch**

A variable unit, defined by statute in different states as the quantity of water that will flow through an orifice of 1 sq. in. area, under a head ranging from 4 1/2 to 6 in. U. S. Reclamation Service defines the miner's inch as 1 cu. in. per sec. The law governing the locality in which the measurement is to be made should be consulted.

### Table 20.—Circular Measure

60 sec. = 1 min.
60 min. = 1 deg.
90 deg. = 1 quad.
360 deg. = circm.
57.2957795 deg. = 1 radian
= 57° 17′ 44.806″
1 radian = angle of arc equal to radius.

### Table 21.—Time

60 sec. = 1 min.
60 min. = 1 hr.
24 hr. = 1 day
7 days = 1 week
52 weeks = 1 year
1 year (exact) = 365 days, 5 hr., 48 min., 45.6 sec.

A year divisible by 4 is a leap year and contains 366 days, except centesimal years, of which only those divisible by 400 are leap years.

365.24734 mean solar days = 1 yr.
= 366.008515 sidereal days
24 hr. mean solar time
= 23 hr. 56 min., 49.9 sec. sidereal time
1 mean solar day
= 1 mean sidereal day + 3 min., 10.1 sec.

## THE METRIC SYSTEM

The fundamental standard of length in the metric system is the International Standard Meter, derived from the Metre des Archives, Paris. Its length is defined as the distance between two lines at 0° C. on a platinum-iridium bar deposited at the International Bureau of Weights and Measures near Paris. 1 meter = 39.37 in.

The fundamental standard of mass is the International Standard Kilogram, which is a mass of platinum-iridium, deposited at the International Bureau, whose weight *in vacuo* is the same as that of the Kilogram des Archives.

The fundamental unit of volume is the **liter,** which is defined as the volume of a kilogram of water at the temperature of maximum density, 4° C., under a pressure of 76 cm. of mercury. The liter originally was defined as a cubic decimeter, but is slightly greater. The generally accepted relation between the cubic decimeter and the liter is 1 liter = 1.000027 cu. decimeters.

The unit of force is the **dyne,** which is the force which acting for 1 second on a mass of one gram will produce a velocity of 1 centimeter per second. 1 dyne = (1/980.665) gram. 1,000,000 dynes = 1.020 kilograms force = 2.248 lb. force. 1 lb. force = 0.4536 kilogram force = 444,800 dynes.

The unit of heat is the **gram-calorie,** which is the quantity of heat required to raise 1 gram of water 1° C. See p. 3–17.

### Table 22.—Units of Metric Measures*

| Length | | | Area | | |
|---|---|---|---|---|---|
| Unit | Symbol | Value in Meters | Unit | Symbol | Value in Sq. Meters |
| Micron | $\mu$ | 0.000 001 | | | |
| Millimeter | mm. | 0.001 | Sq. millimeter | sq. mm. | 0.000 001 |
| Centimeter | cm. | 0.01 | Sq. centimeter | sq. cm. | 0.000 1 |
| Decimeter | dm. | 0.1 | Sq. decimeter | sq. dm. | 0.01 |
| Meter (unit) | m. | 1.0 | Sq. meter (centiare) | sq. m. | 1.0 |
| Dekameter | dkm. | 10.0 | Sq. dekameter (are) | sq. dkm. | 100.0 |
| Hectometer | hm. | 100.0 | Hectare | ha. | 10,000.0 |
| Kilometer | km. | 1,000.0 | Sq. kilometer | sq. km. | 1,000,000.0 |
| Myriameter | Mm. | 10,000.0 | | | |
| Megameter | .... | 1,000,000.0 | | | |

| Cubic Measure | | | Volume | | |
|---|---|---|---|---|---|
| Unit | Symbol | Value in Cubic Meters | Unit | Symbol | Value in Liters |
| Cubic kilometer | cu. km. | 1,000,000,000 | Milliliter | ml. | 0.001 |
| Cubic hectometer | cu. hm. | 1,000,000 | Centiliter | cl. | 0.01 |
| Cubic dekameter | cu. dkm. | 1,000 | Deciliter | dl. | 0.1 |
| Cubic meter | cu. m. | 1 | Liter (unit) | l. | 1.0 |
| Cubic decimeter | cu. dm. | 0.001 | Dekaliter | dkl. | 10.0 |
| Cubic centimeter | cu. cm. | 0.000 001 | Hectoliter | hl. | 100.0 |
| Cubic millimeter | cu. mm. | 0.000 000 001 | Kiloliter | kl. | 1,000.0 |
| Cubic micron | $\mu^3$ | $0.0_{17}1$ | | | |

| Weight | | | | | |
|---|---|---|---|---|---|
| Unit | Symbol | Value in Grams | Unit | Symbol | Value in Grams. |
| Microgram | $\gamma$ | 0.000 001 | Gram (unit) | g. | 1.0 |
| Milligram | mg. | 0.001 | Dekagram | dkg. | 10.0 |
| Centigram | cg. | 0.01 | Hectogram | hg. | 100.0 |
| Decigram | dg. | 0.1 | Kilogram | kg. | 1,000.0 |
| Gram (unit) | g. | 1.0 | Myriagram | Mg. | 10,000.0 |
| | | | Quintal | q. | 100,000.0 |
| | | | Ton | t. | 1,000,000.0 |

---

* A subscript after a figure indicates the number of times it is repeated. Thus $0.0_38 = 0.0008$

### Table 23.—Metric Equivalents of Length *

| English to Metric | | | Log. | Metric to English | | | Log. |
|---|---|---|---|---|---|---|---|
| 1 inch | = 25.4 | mm. | 1.404834 | 1 mm. | = 0.03937 | in. | $\bar{2}.595165$ |
| | = 2.54 | cm. | 0.404834 | | = 0.003281 | ft. | $\bar{3}.515984$ |

---

* A subscript after a figure indicates the number of times it is repeated. Thus $0.0_38 = 0.0008$.
† 1 poncelet = 100 kg.-m. per sec. ‡ 1 cheval-vapeur = 75 kg.-m. per sec. = 1 metric horsepower.

# INDEX

**Note: The double numbers refer to both section and page numbers. For example, 13–09 indicates page 09 of Section 13.**

---

In order to prevent this index from growing to unwieldy proportions, the various properties of the metals and alloys, as tensile strength, specific gravity, specific heat, modulus of elasticity, yield point, etc., are not indexed separately. They are included under the general head of properties of the individual metals and alloys.

## A

- **Abrasion,** gear, 14–16
  - resistance, alloys for, 4–19
    - refractories, 5–08
    - stainless steel for, 3–22
- **Abrasive, abrasives**
  - airless, casting cleaning, 20–38
  - cut-off discs, 21–102
  - grain size, 21–66, 21–92
  - head, polishing wheels, 21–90
  - polishing, 21–92
  - **processes,** 21–66 to 21–96
    - bibliography, 21–66
    - buffing, 21–92 to 21–96
    - honing, 21–88
    - lapping, 21–87
    - polishing, 21–88 to 21–92
  - types of, 21–66
  - **wheel, wheels,** 21–66
    - bond, 21–66
    - care of, 21–78
    - causes of breakage, 21–80
    - diamond, 21–68
    - disc, for surfacing, 21–75
    - factor of safety, 21–80
    - factors influencing selection, 21–70
    - glazing, 21–81
    - grade, 21–67
    - grain depth of cut, 21–76
    - guards, 27–07
    - loading, 21–81
    - marking, 21–67
    - mounting, 21–79
    - operating speed, 21–80
    - polishing, 21–88 to 21–92; *see* Polishing wheels
    - protection, 21–81, 21–82, 21–84
    - resinoid bond, 21–67
    - rubber bond, 21–66
    - selection, 21–66, 21–68
    - shellac bond, 21–66
    - silicate bond, 21–66
    - speed, 21–68
    - spindle sizes, 21–81
    - starting, 21–78
    - structure, 21–67
    - symbols, 21–67
    - synthetic resin bond, 21–66
    - troubles, 21–81
    - vitrified bond, 21–66
    - wear, 21–76, 21–81
- **Absorption** capacity of wood, 22–31
  - dynamometers, 24–83
  - noise, in ducts, 16–24
  - sound, 16–23
- **A. C. motor, motors**
  - adjustable speed, brush shifting, 25–32
  - **control,** polyphase induction motors, 25–54
    - single-phase motors, 25–53
    - squirrel-cage motors, 25–54
    - synchronous motors, 25–59
    - wound-rotor motors, 25–56
  - costs, 25–23, 25–28, 25–38, 25–43
  - dimensions, 25–23, 25–26, 25–38, 25–43
  - full load current, 25–14
  - **polyphase,** application, 25–50
    - **induction,** large-power, 25–28
      - large-power, adjustable varying speed, brush shifting, 25–33
      - large-power, constant horsepower, 25–30
      - large-power, constant torque, 25–30
      - large-power, costs, 25–38
      - large-power, crane, 25–32
      - large-power, dimensions, 25–38
      - large-power, efficiency, 25–33
      - large-power, elevator, 25–32
      - large-power, frame sizes, 25–31
      - large-power, hoist, 25–32
      - large-power, horsepower, 25–29
      - large-power, mechanical features, 25–35
      - large-power, multi-speed, squirrel-cage, 25–30
      - large-power, multi-speed wound-rotor, 25–31
      - large-power, operating characteristics, 25–33
      - large-power, quiet-operating, 25–31
      - large-power, service factor, 25–33
      - large-power, speed ratings, 25–29
      - large-power, squirrel-cage, 25–28
      - large-power, squirrel-cage, frame sizes, 25–31, 25–34 to 25–37
      - large-power, starting current, 25–29, 25–34
      - large-power, temperature rise, 25–33
      - large-power, torque, 25–29, 25–34
      - large-power, variable torque, 25–30
      - large-power, voltage variation, 25–34
      - large-power, weights, 25–38
      - large-power, wound-rotor, 25–30
      - large-power, wound-rotor, frame sizes, 25–32
    - **small-power,** high-frequency, 25–20

**A. C. motor, motors,** *(cont.)*
**small-power,** (*cont.*)
reluctance, 25–20
squirrel-cage induction, 25–20
synchronous, 25–20
**synchronous,** large power, costs, 25–43
large-power, dimensions, 25–43
large-power, efficiency, 25–41
large-power, high-speed, 25–39
large-power, high torque, 25–40
large-power, horsepower, 25–39
large-power, low-speed, 25–39
large-power, mechanical features, 25–43
large-power, operating characteristics, 25–40
large-power, power-factor, 25–40
large-power, speed ratings, 25–39
large-power, standard rating, 25–39
large-power, starting current, 25–42
large-power, synchronous induction, 25–40
large-power, temperature rise, 25–40
large-power, torque, 25–41
large-power, voltage variation, 25–42
large-power, weights, 25–43
**single-phase,** applications, 25–50
**large power,** 25–23, 25–24
brush shifting, repulsion, 25–25
capacitor, 25–25
costs, 25–28
dimensions, 25–26
efficiency, 25–25
frame sizes, 25–26
operating characteristics, 25–25
temperature rise, 25–25
torque, 25–26
voltage variation, 25–26
weights, 25–26
repulsion-induction, 25–24
repulsion-start induction, 25–24
**small power,** 25–18
capacitor, 25–19
capacitor-start, 25–19
repulsion-induction, 25–19
repulsion-start induction, 25–19
series-wound, 25–20
shaded-pole, 25–19
slip, 25–12
**small power,** hysteresis, 25–20
reluctance, 25–20
speeds, 25–18
split-phase, 25–19
standard ratings, 25–18
synchronous, 25–20
starting current, 25–15, 25–21, 25–26, 25–34, 25–42
synchronous speeds, 25–12
torque, 25–14, 25–22, 25–26, 25–34, 25–41
vertical, frame sizes, 25–28
voltage ratings, 25–11
variation, 25–22, 25–34, 25–42
weights, 25–23, 25–26, 25–38, 25–43
Acacia, specific gravity and weight, 5–21
**Acceleration,** def., 8–19
angular, def., 8–19
cranes, 23–31, 23–32
curves, 8–19
due to gravity, 8–20
force of, 8–20
formulas, 8–20
reciprocating parts, graphical analysis, 11–14
resistance to, 8–20
uniform, cam motion, 8–12
work of, 8–21
Acetate of lime, properties, 1–04
Acetic acid, absorption by rubber, 5–31
properties, 1–04, 1–12
Acetone, absorption by rubber, 5–31
Acetylene, properties, 1–13
welding, 2–50
**Acid, acids**
alloys resistant to, 4–19
mine water, stainless steel for, 3–22
organic, effect on zinc, 4–11
process, iron melting, 20–19
resistance, corrosiron, 3–24
copper-aluminum-iron-bronze, 3–25
-resisting brick, 5–14
specific gravity, 1–12
stains, 22–28
steel, 2–10, 2–11
-still castings, analyses, 20–08
Acme thread, 9–03
Acoustic filters, 16–24
Actinium, atomic weight, 1–03
Acuity, visual, 26–15
Adapter sleeve, ball bearing, 13–82
Addendum, bevel gears, 14–22
helical gears, 14–19
**Adhesives** (*see also* Glue)
plywood, 22–25
resin, film, 22–26

  aluminum, 4–48
  cranes, 23–16
  def., 6–27
  hoist-conveyors, 23–15
Cableways, 23–15
**Cadmium,** atomic weight, 1–03
  compressibility, 1–16
  effect on zinc, 4–11
  light, wave lengths, 21–111
  properties, 1–05, 1–08
Caisson, foundation, 17–13
  piles, 17–11
Calcite, hardness, 1–15
**Calcium,** atomic weight, 1–03
  compounds, 1–04
  compressibility, 1–16
  properties, 1–05, 1–08
Calimine, hardness, 1–15
Calipers, 21–107
Calsun bronze, properties, 4–32
  wire properties, 6–20
**Cam, cams,** 8–11
  castings, hardened, 20–22
  correction for roller follower, 8–14
  cylindrical, 8–14
    rollers, 8–14
  follower, rocker, 8–13
  gaging, 21–110
  grinding, 21–71
    machines, 21–85
  harmonic-motion, 8–12
  minimum radius of curvature, 8–14
  offset follower, 8–13
  rocker-follower, 8–13
  rollers, grinding, 21–71
  -shaft bearings, grinding, 21–71
    steel for, 2–38
  steel for, 2–38, 2–39
  uniform-acceleration, 8–12
  uniform-motion, 8–11, 8–12
Camel-hair belting, coefficient of friction, 24–36
Candle, def., 26–13
Candlepower, def., 26–13
Cannel coal, weight, 5–37
Cannery equipment, stainless steel for, 3–22
Cantilever beams, 7–18, 7–30
Canvas belts, 24–36, 24–37
Cap, alloy for, 4–24
  gilding, properties, 4–28
  screw, *see* Screws, cap
Capacitor, def., 25–03
Capacity, metric equivalents, 28–55
**Car, cars**
  axles, forging equipment, 19–05
    steel specifications, 2–24
  castings, analyses, 20–08
  coal, time required to unload, 23–49
  couplers, proof tests, 7–59
  dumper, 23–34, 23–49
  haulage, mine, 23–59
  hopper and gondola, corrosion of, 3–07
  industrial, bearings, 13–82, 13–92
  ingot, bearings, 13–82
  journal lubricants, 13–55
  kiln, 22–21
  loaders, 23–64, 23–65
  pullers, 23–45
  spotters, 23–45
  steel specifications, 2–22
  unloaders, 23–65, 23–68
  wheel castings, analyses, 20–08
    noise, 16–20
Carat weight, 28–52
Carbide, cemented, *see* Cemented-carbide
  of iron, 2–12
Carbolic acid, specific gravity, 1–12
Carbolon, 5–12

- **Carbon,** 5–31 to 5–36
  - -arc welding, 2–51, 5–36
  - atomic weight, 1–03
  - baking furnace, refractories for, 5–17
  - bricks, 5–34
    - required to form various circles, 5–35
  - brushes, 5–32
  - combined, in cast iron, 2–04
  - compounds, 1–04
  - compressibility, 1–16
  - **dioxide,** absorption by rubber, 5–30
    - compressibility, 1–16
    - effect on zinc, 4–11
    - properties, 1–13
  - disulphide, absorption by rubber, 5–31
    - specific gravity, 1–12
  - effect on cast iron, 2–04, 20–06
    - on steel, 2–11
  - electrodes, 5–33
  - in malleable castings, 20–40
  - lighting, 5–34
  - monoxide, absorption by rubber, 5–30
    - properties, 1–13
  - paste, 5–36
  - properties, 5–32
  - Raschig rings, 5–34
  - residue, oil, 13–54
  - spectroscopic, 5–34
  - steel; *see* Steel, carbon
  - tetrachloride, absorption by rubber, 5–31
  - welding products, 5–36
- Carborundum, 5–12, 21–66
- Carburized parts, steel for, 2–38
- Carburizing furnace, fuel consumption, 18–05
- **Cargo** boats, drag-scrapers in, 23–17
  - cranes, 23–36
  - hoists, 23–44
  - hook, 23–12
- Carpet, sound absorption, 16–23
- Carriage bolts, 9–31

    shafting, 24–03
    threads, 9–03
    variable-speed drives, 24–72 to 24–79; *see* Variable-speed Drives
    wire-rope, 24–53
Praseodymium, atomic weight, 1–03
Pratt truss, 17–04, 17–44
Precast slab roofs, 17–40
Precipitation heat treatment, aluminum alloys, 4–42
Precipitator, electrostatic, dust, 26–05
  spiral tube, dust, 26–07
Preece test, 3–16
Preservation of timber, 5–22
Preservatives, wood, 22–29
Press, presses
  blank holding devices, 21–61
  castings, printing, analyses, 20–09

**Press, presses,** (*cont.*)
  cold-working, 21–64, 21–65
  drawing, 21–58
  fly-wheel slow-down, 21–64
  forging, 19–18, 19–22
  gear reductions, 21–57
  gluing, 22–27
  guarding, 27–07
  hydraulic, 19–16 to 19–20; *see* Hydraulic press
  inclinable, 21–57
  mechanical power, 21–57
  metal-briquetting, 20–17
  percussion, 21–57
  plywood bending, 22–33
  pneumatic die cushions, 21–61
  punch, 21–64, 21–65
    motors, 21–105
  rubber bumpers, 21–61
  steam-hydraulic, 19–17, 19–20
  toggle joint, 21–57
  trimming, 19–11, 21–59
  upright, 21–57
**Pressure, pressures**
  air, cupola, 20–10
    oil burners, 18–10
  -angle, bevel gears, 14–22
  blank holding, shell drawing, 21–61
  blast, cupola, 20–11
  castings, analyses, 20–09
  collapsing, of tubes, 7–45, 7–46
  control, 15–12
  external, strength of cylinders under, 7–45, 7–47
  film, journal bearings, 13–29
  forging, 19–04
  internal, on cylinders, 7–44, 7–47
  metric equivalents, 28–56
  -resistance, alloys for, 4–19
  riveting, 9–48
  screw-down, metal rolling, 21–59
  tool, 21–13
    planers, 21–28
  -velocity relations, journal bearings, 13–32
  wind, on roofs, 17–38
  -working, metals; *see* Metals, pressure working
Prevention, corrosion, 3–11
  noise, 16–20
Primer gilding, 4–24, 4–26
Primers, alloys for, 4–24
Printing machinery, belt service factors, 24–18, 24–30
  press castings, analyses, 20–09
Prism, center of gravity, 8–16
  moment of inertia, 8–17
  radius of gyration, 8–18
**Processes,** abrasive, 21–66 to 21–96
  corrosion resisting, 3–13
  industrial, furnace temperature ranges, 18–03
    heating, 18–03 to 18–28
Producer-gas burners, 18–13
    fuel, industrial furnaces, 18–07
    generators, refractories, 5–18
Products, aluminum, 4–47
  automatic machine, steel for, 2–38
  steel, specifications, 2–21 to 2–37
Production, economic, 21–13
  relation of illumination, 26–16
Profile dies, 21–59
Profiling machines, 21–46
Profilograph, 21–113
Profilometer, 21–113
Program regulation, 15–13
Progression, geometrical; *see* Geometrical progression
Projectile castings, analyses, 20–09
Prony brake, 24–82, 24–83
Proof coil, 6–30
  tests, def., 7–58
    quenched and tempered forgings, 2–30
**Propeller, propellers**
  airplane, balancing, 16–08
    forging equipment, 19–05
  alloys for, 4–19, 4–24
  castings, analyses, 20–09
  shafts, steel for, 2–39
    thrust bearings, 13–42
**Properties,** acid-resisting alloys, 3–24, 3–25
  aluminum, 4–34
    structural sections, 6–12 to 6–15
    wire, 6–23
  calsun bronze wire, 6–20
  chain, physical, 6–30

  magnesium alloys, 4–55, 4–57
  nickel, 4–49
  nickel-silver, 4–54
  numbers, table, 28–25
  physical, determination by magnetic permeability, 7–59
  physical, gases, 1–13
    metals, 4–05, 4–07
  plastic, metals, 21–56
  refractories, 5–08
  resistance alloys, 4–55
  rubber, 5–27
  stainless steel, 3–20
      springs, 10–04
  structural sections, 17–47 to 17–81
  telegraph and telephone wires, 6–18
  trolley wire, 6–22
  wide-flange beams, 17–50
  wood, 5–20
  zinc, 4–11
    rolled, 4–15
Proportional limit, def., 7–04
    relation to endurance limit, 7–12
Protection, bands, abrasive wheel, 21–84
  chucks, abrasive wheels, 21–84
  electric motor, 25–51, 25–52
  eye, 27–09
  fire, blower systems, 23–68
  flanges, abrasive wheel, 21–82
  head, 27–09
  hoods, abrasive wheels, 21–81
  wire rope, 6–35
Protoactinum, atomic weight, 1–03
Public buildings, live load requirements, 17–12
Puddle furnace, refractories for, 5–20
  iron, 2–04
Pulls, mold, in castings, 4–08
Pull-in torque, synchronous motors, 25–14, 25–41
Pull-out torque, synchronous motors, 25–14, 25–41
Pull-up torque, A.C. motors, 25–14
Pullers, car, 23–45
**Pulley, pulleys,** 24–08 to 24–13
  arms, 11–21, 24–08
  arrangement of, 24–24
  cast-iron, proportions, 24–08
    relative capacity, 24–09
    weight, 24–09
  castings, analyses, 20–09

**Pulley, pulleys,** (*cont.*)
  compressed spruce, 24–09
  cone, 24–12, 24–13
  cork insert, 24–09
  crowning, 24–09
  differential, 8–05
  grinding, 21–72
  guide, 24–25
  hub, 24–08
  idler, 24–24
  lagged, 24–09
    coefficient of friction, 23–62
  machine element, 8–04
  mule, 24–26
  paper, relative capacity, 24–09
  Reeves vari-speed, 24–78
  spacing, 24–36
  steel, relative capacity, 24–09
  steel split, 24–09, 24–11, 24–12
  width, 24–09, 24–20
  windage, 24–10
  wood-face, 24–09, 24–11
Pulverized coal, dust concentration, 26–11
  coal, handling, 23–48
  material, conveying, 23–68
Pulverizer bearings, 13–92
Pumice, specific gravity and weight, 1–12
**Pump, pumps**
  alloys for, 4–19
  bearings, 13–92
  bodies, alloys for, 4–19
  castings, analyses, 20–09
  centrifugal, motors for, 25–50
  Fluxo, 23–69
  Fuller-Kinyon, 23–69
  parts, stainless steel for, 3–22
  vacuum, motors for, 25–50
  V-belt service factor, 24–30
Pumping machinery, fly-wheels, 11–15
**Punch, punches**
  differential screw, 8–11
  hydraulic press, 19–16
  press guards, 27–07
    motors, 21–105, 25–50
  presses, 21–64, 21–65
Punching, stainless steel, 3–23
Purlins, roof, 17–38, 17–39
Pyramid, center of gravity, 8–16
  frustum, center of gravity, 8–16
  hardness testing machine, 1–13
Pyrite, hardness, 1–15
  iron weight, 5–37
Pyrometer protection tubes, stainless steel for, 3–22
Pyrometric cone equivalent, 5–03
    refractory brick, 5–05
  softening points, 5–03

## Q

Quadrant, center of gravity, 8–16
  of ellipse, center of gravity, 8–16
Qualification tests of welders, 2–60
Quarry hoists, 23–44
Quarter-sawn lumber, 22–05
Quarter-twist belts, 24–25
Quartz, broken, weight, 5–37
  hardness, 1–15
Quartzite, 5–06
Quaternary alloys, 2–18
Queen-post truss, 17–03
Quench-temperatures, alloys, 4–07
**Quenching,** cast iron, 20–21
  oil, 2–16
**Quenching,** (*cont.*)
  steel castings, 20–27
  tool steel, 21–27
Quicklime, 1–04
Quill bearings, 13–85

## R

Rabble arms, stainless steel for, 3–22
Races, ball and roller, steel for, 2–39
Radians, value in degrees, 28–44
Radiator, automobile, alloys for, 4–24
  castings, analyses, 20–09
  valves, alloy for, 4–19
Radio parts, alloy for, 4–24
Radium, atomic weight, 1–03
**Radius of gyration,** columns, 7–34, 17–77
  def., 8–18
  polar, 7–41
  steel angles, 17–65 to 17–67
    beams, 17–50, 17–58
    channels, 17–62
    columns, 17–77
    tees, 17–71
    zees, 17–72
  two angles, 17–65
  various sections, 7–20, 7–21, 8–18
Radius of oscillation, 8–22
Radon, atomic weight, 1–03
Rails, carbon steel, drop test, 2–37
  dry kiln, 22–21
  sawing, speeds, 21–102
  stair, 27–09
  steel, specifications, 2–22
**Railroad, railway**
  axles, grinding, 21–71
  cars, bearings, 13–31
    brake beam tests, 7–59
    journal lubricants, 13–55
    springs, 10–18
      alloy-steel, specifications, 2–22
      material for, 10–03
    suspensions, 16–17
  castings, alloy-steel, specifications, 2–26
    analyses, 20–09
    corrosion, 3–07
  crossties, preservation treatments, 5–22, 22–31
  forge shop arrangement, 19–14
  spikes, resistance, 9–46
  track clearance, 27–09
    coefficient of rolling friction, 8–27
Rake-angles, cutting tools, 21–10
  milling cutters, 21–41
Ramsey-Pulvis clutch, 24–64
Range, critical, metallography, 4–04
  plastic, 21–55
  softening, of metals, 4–06
Rankine's column formula, 7–35, 7–39
Rape-oil, coefficient of friction, 8–30
  specific gravity, 1–12
Raschig rings, 5–34
Rates, electric power, 25–07
**Rating,** ball bearings, 13–72
  crane, 23–27
  electric motors, 25–06, 25–09, 25–11, 25–24, 25–29, 25–39, 25–44 to 25–46
  load-life, ball bearings, 13–67
  voltage, A.C. motors, 25–11
Ratio, Poisson's, 7–06
  speed, silent chains, 24–46
Reactions, beams, 7–18
Reamers, for aluminum, 4–44
  grinding, 21–72

Rear-axle gearing, steel for, 2–39
Reaumur thermometer scale, 28–50
Reciprocals of numbers, table, 28–25
Reciprocating parts, determination of velocity and acceleration, 11–14
Reclamation, sheet scrap, 20–19
**Rectangle, rectangles**
  area of, 6–06
  crossed, elements of, 7–21
  elements of, 7–20
  hollow, elements of, 7–20
Recuperator, industrial furnaces, 18–19
  parts, stainless steel for, 3–22
  refractories for, 5–20
Red-brass, properties, 4–21, 4–26
  leaded, properties, 4–28
Red-lead, 1–04, 3–12
Red-shortness in cast iron, 2–04
Redler conveyor, 23–58
Reducer, gear-, ball bearing, 13–81
  speed, 24–69 to 24–72; *see* Speed reducers
Reduction-gear bearing, 13–31
**Redwood,** allowable unit stresses, 7–28, 7–29
  characteristics and uses, 5–22
  joists, safe loads, 17–34
  nail-holding power, 9–45
  plywood, properties, 5–25
  specific gravity and weight, 5–21
  structural timber, working stresses, 17–35
  viscosity, 13–57
Reed frequency meter, 16–04
  taper, 12–20
Reef knot, 6–28, 6–30
Reeves variable speed transmission, 24–75
  vari-speed pulley, 24–78
Reflectance, def., 26–13
Reflection-factor, def., 26–13
Reflectivity, aluminum, 4–34
  magnesium, 4–55
**Refractories,** 5–03 to 5–20
  abrasion resistance, 5–08
  acid resisting brick, 5–14
  applications of, 5–17
  carbon bricks, 5–34
  cold crushing, strength, 5–08
  digester brick, 5–16
  Duro, 5–16
  electric furnaces, 18–26
  electrical resistivity, 5–09
  firebrick required for various circles, 5–15
  Forsterite brick, 5–16
  grinding, 21–75
  high-alumina, analyses, 5–05
  insulating brick, 5–16
  modulus of rupture, 5–08, 5–09
  mortar for, 5–10, 5–11
  properties, 5–08
  resistance to slagging, 5–09
  silicon-carbide, 5–12
  spalling resistance, 5–09
  specific gravity, 5–10
    heat, 5–10
  thermal properties, 5–08
Refractoriness, firebrick, 5–03
Refrigerating compressors, motors for, 25–50
Refrigerator castings, analyses, 20–09
Regenerator, industrial furnaces, 18–19
**Regulation,** 15–03 to 15–14
  asymptotic, control mechanisms, 15–06
  isoposic, control mechanisms, 15–06
  program, 15–13
  speed, electric motors, 25–09
  voltage, 25–07
Regulator, feedwater, 15–08
  pressure, 15–08
Reinforcement, concrete arches, 17–25
Reist thrust bearing, 13–36, 13–43
**Relay control,** 15–04
  governing, 15–12
  overload, electric motors, 25–51
  resets, 25–52
Release, under-voltage, 25–52
Relief, stress, of metals, 4–06
Relief-angles, cutting tools, 21–08, 21–11
Repeated stress, 7–11
Repose, angle of, 8–24
Resaws, band, 22–12
Resets, relay, 25–52
Residences, cost of, 17–46
  noise level, 16–19
Resilience, cork, 5–25
  def., 7–07
  modulus of, 7–07
    springs, 10–21
    various materials, 7–08
**Resin-bonded bearings,** 13–50
  -film adhesives, 22–26
  -oil, absorption by rubber, 5–31
    specific gravity, 1–12
**Resistance**
  alloys, 4–07, 4–54, 4–55
  band brakes, 15–17
  corrosion, steel for, 2–39
  dynamic stresses, steel for, 2–39
  fatigue, cast iron, 20–05
  fatigue, steel for, 2–39
  furnaces, 18–22
  haulage systems, 23–14
  impact, cast iron, 20–05
  railroad spikes, 9–46
  rolling, trailers, 23–78
  wear, cast iron, 20–03
    steel for, 2–40
  welding, 2–48
    symbols, 2–54
  wood screws, various woods, 9–46
Resisting moment, 7–19, 7–40
Resistivity, electrical, *see* Electrical resistivity
Resistors, electric furnace, 18–22
Resonance, 16–03
  helical springs, 16–13
Response, speed of, control mechanism, 15–06
Rest, friction of, 8–25
Retarder, wire-rope, 23–60
Retort castings, analyses, 20–09
Reverberatory furnaces, refractories for, 5–20
Revolvator, 23–74
Reyn, 13–44
Rhenium, atomic weight, 1–03
Rheostats, alloys for, 4–53
Rhodium, atomic weight, 1–03
  properties, 1–06
Ribbon zinc, 4–13
Richards relation, 4–07
Riehle testing machine, 7–52
Rigidity, modulus of, 7–06
Rims, fly-wheels; *see* Fly-wheels
**Ring, rings**
  chain, 6–33
  circular, moment of inertia, 8–17
    radius of gyration, 8–18
  comb-, bearing closures, 13–08
  crown-, bearing closures, 13–09
  felt, bearing closures, 13–08
  gages, 21–111
  gears, steel for, 2–40
  packing, bearings, 13–09

**Ring, rings,** *(cont.)*
  piston-, grinding, 21–72, 21–75
  Raschig, 5–34
  seal, bearings, 13–09
  snap, steel for, 2–40
Riprap, specific gravity and weight, 1–12
Risers, stair, 17–14
River logging, 22–03
**Rivet, rivets,** 6–47 to 6–50, 9–47 to 9–54
  alloys for, 4–24
  aluminum, 4–45, 6–49
  arrangement of, 9–48
  bearing values, 17–79
  belt, 6–49
  burrs, 6–50
  coopers', 6–49
  forging equipment, 19–05
  heads, 9–47
  holes, 4–45, 9–47
  length required for various grips, 17–80
  materials, 9–48
  pitch, riveted joints, 9–48, 9–50, 17–16
  pressure required to drive, 9–48
  proportions in building construction, 17–16
  shearing and bearing value, 17–79
    strength, 9–48
  size, in riveted joints, 9–49
  small, dimensions, 6–49
  spacing, building construction, 17–16
  steel, 2–22, 2–40
    allowable stresses, 17–15
  strength, 9–48
  tests, 7–59
  tinners', 6–50
  weight, 6–47, 6–48
**Riveted-joints,** 9–49 to 9–54
  double-riveted butt-, 9–51
  double-riveted lap-, 9–50, 9–51
  efficiency, 9–50
  formed by more than two plates, 9–49
  lap-riveted girth-, 9–52
  pitch of rivets, 9–49, 9–50, 17–16
  plates in different planes, 9–49
  precautions in making, 9–53
  quadruple-riveted butt-, 9–51
  single-riveted lap-, 9–50, 9–51
  size of rivet, 9–49
  strength, 9–50
  tests, 7–59
  triple-riveted butt-, 9–51
**Riveting,** aluminum, 4–45
  chain, 9–48
  ingot iron, 2–10
  magnesium alloys, 4–58
  staggered, 9–48
  stainless steel, 3–24
  steel for, 2–40
  structural steel, 17–79
  symbols for, 17–80
Roads, rolling resistance of, 23–78
Roasters, refractories for, 5–20
**Rock** crushers, belt service factors, 24–18, 24–30
  elevators, 23–57
  loads, permissible, 17–10
  -salt, hardness, 1–15
  -wool, sound absorption, 16–23
Rockers, expansion, permissible bearing stress, 17–15
Rockwell hardness, 1–13
  conversion table, 1–14
Rockwood drive, 24–32
**Rod, rods**
  aluminum, 4–47
**Rod, rods,** *(cont.)*
  brass, alloy for, 4–24
    weight, 6–11
  copper, alloys for, 4–24
    weight, 6–12
  Everdur, 6–11
  magnesium alloy, 4–56
  piston, 4–24
  solid, moment of inertia, 8–17
    radius of gyration, 8–18
  steel for, 2–40
  swaged tungsten, 4–59
  weight, various materials, 6–03, 6–09 to 6–12
  welding, 4–24, 20–09
**Roll, rolls**
  bending and straightening, 21–60, 25–50,
  castings, analyses, 20–09
  -feed, guards, 27–07
    sanders, 22–47
  grinding, 21–72
    machines, 21–84
  neck bearings, 13–31, 13–48
**Roller, rollers**
  -bearings, 13–82 to 13–94
    dimensions, load capacities, 13–83 to 13–91
    flanged cup, 13–90
    friction of, 8–31
    grinding, 21–72, 21–75
    life, 13–92
    lock-nuts, 13–88
    lock-washers, 13–88
    lubrication, 13–83, 13–93
    mounting, 13–92
    multiple-row, 13–90
    needle, 13–85
    races, steel for, 2–40
    service factors, 13–82, 13–92
    solid, 13–85
    steel for, 2–38
    steep-angle, 13–90
    straight roller, 13–82
    tapered, 13–89
      load factor, 13–82, 13–92
    wound roller, 13–82
  cam, grinding, 21–71
  chain, chains, 24–38 to 24–45
    best conditions of driving, 24–42
    dimensions, 24–39, 24–40
    elongation, 24–43
    horsepower, 24–40
    idler sprocket, 24–43
    lengths, 24–42
    loads, 24–40, 24–42
    maximum impact, 24–41
      velocity, 24–41
    pitch, 24–41
    proportions, 24–41
    selection, 24–42
    slack, 24–42
    sprocket, cutters, 24–45
      distance, 24–42
      number of teeth, 24–45
      proportions, 24–43
      selection, 24–42
      standard diameters, 24–44
      tolerances, 24–43
      tooth dimensions, 24–44
    standard, 24–40
      numbers, 24–42
    tolerances, 24–42
  conveyor, 23–73
  cylinder cams, 8–14
  expansion-, permissible bearing stress, 17–15
  spherical, 7–50

- **Roller, rollers,** (*cont.*)
  - -spider, milling, 21–43
  - steel for, 2–40
  - strength of, 7–50, 7–51
- **Rolling,** effect on metals, 4–06
  - forge-, 21–58
  - hitch, 6–29
  - metal, contact area, 21–59

  - galvanized, galvanizing test, 6–18
    - telegraph and telephone, 6–16
  - hard drawn, steel for, 2–39
  - jeweler's, alloy for, 4–54
  - molybdenum, 4–60
  - non-ferrous, 6–19 to 6–23
  - phosphor-bronze spring, fiber stress, 10–12
  - piano, strength, 6–17
  - pin, alloys for, 4–25
  - plow steel, 6–16
  - -rope, 6–34 to 6–47
    - airplane strand and cord, 6–37
    - attaching, 23–10
    - bending stresses, 23–06
    - blocks, 23–05
    - breaking strength, 6–34
    - clamps, 6–45
    - clips, 6–45, 23–10
    - deterioration, 23–09
    - discarding, 23–09
    - drums, 6–34, 23–07
      - diameter ratios, 23–08
    - elevator, 6–41
    - exposure to heat, 6–36
    - extra flexible hoisting, 6–38, 6–39
    - failure, 23–09
    - fastening to drum, 23–10
    - fittings, 6–44 to 6–46
    - flat, 6–42
    - flattened strand, 6–39, 6–40
    - friction, 23–08
    - galvanized, 6–36, 6–37
      - steel strand, 6–37
      - steel bridge strand, 6–36
    - guy, dimensions and strength, 6–36
    - handling, 6–35
    - haulage, 6–37 to 6–39, 23–13
      - flattened strand, 6–39
      - resistance of cars, 23–14
      - rope tensions, 23–14
    - hoisting, 23–04, 23–05
    - internal wear, 23–07
    - lay, 6–34
    - locked coil cable, 6–42, 6–43
      - wire cable, 6–42, 6–43
    - lubrication, 6–35
    - marlin-clad, 6–41
    - non-spinning hoisting, 6–40
    - plow steel bridge cable, 6–36
    - power transmission, 24–53
    - protection, 6–35
    - retarder, 23–60
    - reverse bending, 6–35, 23–07
    - shackles, 6–44
    - sheaves, 6–34, 23–07
      - diameter ratios, 23–08
      - grooves, clearance, 6–35
    - slings, 23–12
    - sockets, 6–45, 6–46, 23–10
    - special flexible, 6–38, 6–39
    - splices, 6–44, 6–46
    - steel-clad hoisting, 6–41

- **Wire, wires,** (*cont.*)
  - rope, (*cont.*)
    - swivels, 23–12
    - tests, 7–59
    - thimbles, 6–44, 23–10
    - towing and running, 6–42, 6–43
    - tramways, 6–42, 6–43, 23–14
    - transmission, 6–37 to 6–39
      - flattened strand, 6–39
    - turnbuckles, 6–45
    - unsafe, 23–09
  - silicon-bronze, 6–19
  - splices, 6–18
  - spring brass, fiber stress, 10–12
  - spring, properties, 10–04
  - square spring, 10–12
  - steel, 2–41, 6–17
  - steel, copper, etc., 6–16 to 6–26
  - telegraph and telephone, 6–16 to 6–19
  - telegraph, joints in, 6–17
  - trolley, properties, 6–22
  - tungsten drawn, 4–59
  - window screen, alloy for, 4–25
- Wiring, crane, 23–30
- Wobble saws, 22–39
- Wolman salts, wood preservative, 22–30
- **Wood, woods,** 5–20 to 5–25
  - absorption capacity, 22–31
  - beams, safe loads, 17–34
  - bearings, 13–49
  - **bending,** 22–32 to 22–34
    - cold, 22–33
    - dry, 22–32
    - hot, 22–33
    - plywood, 22–32, 22–33
    - solid, 22–32
    - wet, 22–32
  - -block floors, 17–37
  - case-hardened, 22–21
  - characteristics of various, 5–21
  - classes of, 22–05
  - coefficient of friction, 8–25
    - of rolling friction, 8–27
  - columns, 7–37
    - building, 17–21
  - commercial weights and measures, 5–21
  - composition, 5–20
  - cooking, 22–14
  - cutting theory, 22–34
  - drilling speeds, 21–47
  - drying technique, 22–18
  - equlibrium moisture content, 22–17
  - filling, 22–27
  - finishing, departmental arrangement, 22–28
  - fire-retardant treatment, 22–30
  - fly-wheels, 11–20
  - friction of, 15–20
  - heating value, 5–20
  - impact tests, 7–60
  - joints, fastenings for, 9–54
    - methods of failure, 9–54
  - jointers, 22–43
  - -joist floors, 17–35
  - lacquering, 22–27
  - moisture content tests, 22–19
  - planers, 22–40
  - **preservation,** 22–29 to 22–32
    - equipment and procedure, 22–30
    - non-pressure processes, 22–31
    - pre-conditioning process, 22–30
    - pressure processes, 22–30
    - treatments, specifications, 22–31
  - properties of, 5–20
  - pulleys, 24–09, 24–11
- **Wood, woods,** (*cont.*)
  - resistance of drift bolts in, 9–46
  - resistance of railroad spikes in, 9–46
  - roof trusses, 17–43
  - rubbing, 22–29
  - screws; *see* Screws, wood
  - sound absorption, 16–23
  - specific gravity and weight, 5–21
  - stain, 22–28
  - staining, 22–27
  - steaming, 22–14
  - tests of, 7–59
  - time required to dry, 22–18, 22–19
  - uses, 5–21
  - various, allowable unit stresses, 7–28, 7–29
  - waxing, 22–27
- Wood's metal, hardness, 1–15
- Woodruff keys, 12–05, 12–07
- **Woodworking,** 22–03 to 22–48
  - bibliography, 22–48
  - bits, 22–37
  - dry kiln, 22–17 to 22–21
  - finishing, 22–27
  - logs and logging, 22–03
  - lumber, 22–05
  - **machinery,** 22–39 to 22–48
    - bearings, 13–35, 13–92
    - belt service factors, 24–18, 24–30
    - boring machines, 22–45
    - boring tools, 22–37
    - carving machines, 22–44
    - castings, analyses, 20–09
    - cutter heads, 22–37
      - knives, 22–37
    - dust hoods, 26–08
    - flooring machines, 22–44
    - guards, 27–06
    - hoods, 27–06
    - jointers, 22–43
    - knives, grinding wheels for, 21–72
    - lathes, 22–45
    - manufacturers, 22–48
    - mortising machines, 22–46
    - moulders, 22–43
    - planers, 22–40
    - routers, 22–44
    - sanders, 22–47
    - shapers, 22–44
    - stickers, 22–43
    - tenonning machines, 22–46
  - materials, 22–03 to 22–09
  - plywood and gluing, 22–21 to 22–27
  - primary conversion machinery, 22–09
  - processing, 22–17 to 22–34
  - saw mills, 22–09
  - sequence of machine operations, 22–22
  - small tools, 22–34 to 22–39
  - veneer, 22–07, 22–23
- Wool, ducts for conveying, 26–10
  - sound absorption, 16–23
  - specific gravity and weight, 1–12
- Woolen cloth, coefficient of friction, 8–25
- Work capacity, control mechanisms, 15–06
  - external, 7–07
  - metric equivalents, 28–56
  - of accelerated rotation, 8–21
  - of acceleration, 8–21
  - places, foot-candles, 26–16, 26–17
  - required for rupture, 7–07
  - surface, def., 21–09
- Working stresses, masonry, 17–19
- Workmanship, building construction, specifications, 17–18
- Worms, hobbed, 14–32

**Worm-gear**, 8–09; *see* Gears, worm
  drives, 14–25, 14–28
    loading, 14–33
  speed reducers, 24–72
Worm-gearing, friction of, 8–31
Worm-wheels, alloys for, 4–19
$WR^2$, electric motors, 25–09, 25–10
Wrench clearance, bolt spacing for, 9–30
  heads, grinding, 21–75
  openings, dimensions, 9–30
  socket, 9–35
Wrist-pins, gaging, 21–110
**Wrought-iron**, 2–04 to 2–06
  bars, 2–05, 2–06
    etch and step tests, 2–06
  coefficient of friction, 8–24
  corrosion, 3–06
  cutting fluid, 21–22
  drilling lubricant, 21–48
  factor of safety, 7–11
  grades, 2–04
  grinding, 21–70, 21–74
  hardness, 1–14
  modulus of resilience, 7–08
  pipe, corrosion, 3–07
  plates, 2–04, 2–05
  properties, 2–04
    under repeated stress, 7–12
  specifications, 2–04
  thermal expansion, 7–10
  toughness, 7–08

X

Xenon, atomic weight, 1–03
X-ray examination of fusion welds, 2–52
  inspection, 4–08
  tests, castings and forgings, 7–58
Xylene, absorption by rubber, 5–31

Y

Yard-lumber, 22–05
Yarn, def., 6–27
Yellow brass, properties, 4–22, 4–28
Yield point, def., 7–04
    determination of, 7–56
    relation to endurance limit, 7–12
  strength, def., 7–05
    determination, 7–56
Yielding, alloys and metals, 4–08
Yoke, Scotch, 8–08
Young's modulus of elasticity, 7–05, 21–64
    metals and alloys; *see* material in question
Ytterbium, atomic weight, 1–03
Yttrium, atomic weight, 1–03

Z

Zees, aluminum, 6–14
  steel, 17–72
Zeiss-Dywidag roof construction, 17–44
Zilloy roofing, 4–16
Zinc, atomic weight, 1–03
  bending, 4–17
  boiler plate, 4–14
  castings, shrinkage allowance, 20–10
  chemical characteristics, 4–10
  chloride wood preservative, 22–29
  coatings, 3–16, 4–12
  compounds, 1–04
  compressibility, 1–16
  corrosion, 4–10
  corrugated sheets, 4–16
  cutting fluid, 21–22
  die-casting alloys, 4–13, 4–61
  drawing, 4–17
  dust, 4–13
  dynamic ductility, 4–15
  effect of carbon dioxide, 4–11
    of organic acids, 4–11
    of oxygen concentration, 4–11
    of steam, 4–11
    of various metals, 4–11, 4–12
  enameling, 4–17
  extrusion, 4–17
  fabrication, 4–16
  finishes, 4–17
  furnaces, refractories, 5–18, 5–20
  gage, 4–14
  galvanizing, 4–12, 4–13
  hardness, 1–07, 1–14
  heat content, 18–04
  hull plate, 4–14
  lubrication, 4–16
  machining, 4–17
  -meta-arsenite wood preservative, 22–30
  metallography, 4–11
  modulus of elasticity, 1–07, 4–16
  painting, 4–17
  plastic properties, 21–56
  plating, 4–17, 4–46
  properties, 1–07, 1–10, 4–10
  ribbon, 4–13
  rolled, 4–13 to 4–17
  roofing, 4–16, 17–42
  sawing, 21–102
  sheet, 4–13, 6–10
  sherardizing, 4–13
  slab, 4–12
  slush casting, 4–13
  softening temperatures, 4–06
  soldering, 4–17
  stamping, 4–17
  strength, 1–07, 4–15, 4–16
  temper, 4–15
  tensile tests, 4–16
  testing methods, 4–15
  toxicity, 4–11
  weight, 5–37
  welding, 4–17
Zirconia, 5–38
Zirconium, atomic weight, 1–03
  properties, 1–07

## WILEY ENGINEERING HANDBOOK SERIES

## HANDBOOK OF ENGINEERING FUNDAMENTALS

SECTION Edited by Ovid W. Eshbach. 1081 Pages

1. MATHEMATICAL AND PHYSICAL TABLES: Symbols and Abbreviations; Mathematical Tables; Physical Properties of Materials; Tables of Conversion Factors—Units of Weights and Measures; Gages; Standard Structural Sizes; by Ovid W. Eshbach in collaboration with J. L. Barnes, J. G. Brainerd, R. T. Kent, and H. C. Knutson.
2. MATHEMATICS: Arithmetic; Algebra; Mathematics of Finance; Geometry; Trigonometry; Plane Analytic Geometry; Solid Analytic Geometry; Differential Calculus; Integral Calculus; Differential Equations; Solution of Linear Constant-coefficient Integro-differential Equations by the Laplacian Transformation (Operational Calculus); Functions of Complex Variables; Vector Analysis; Alignment Charts (Nomograms); Precision of Measurements; by J. L. Barnes in collaboration with J. G. Brainerd, C. Eisenhart, M. J. Fish, and J. M. Rice.
3. PHYSICAL UNITS AND STANDARDS: Dimension Systems; Unit Systems; Units and Standards; Dimensional Analysis; by Ernst Weber.
4. THEORETICAL MECHANICS: Statics; Kinematics; Kinetics; by Janvier M. Rice.
5. MECHANICS OF MATERIALS: Simple Stresses; Beams; Columns; Shafts; Cylinders, Plates, Rollers, and Riveted Joints; Testing of Materials; by Jasper O. Draffin. Reinforced Concrete; by Theodore Crane.
6. MECHANICS OF FLUIDS: Properties of Fluids, Divisions of Fluid Mechanics; Fluid Statics; Fluid Dynamics; by P. E. Hemke.
7. ENGINEERING THERMODYNAMICS: Principles of Thermodynamics; Gases; Liquids and Vapors; The Steam Power Plant; The Internal-combustion Engine; Refrigeration; Gas and Vapor Mixtures, Humidity, and Air Conditioning; by Milton C. Stuart and Paul J. Kiefer.
8. ELECTRICITY AND MAGNETISM: Electron Theory; Direct-current Circuits; Electrokinetics and the Magnetic Circuit; Electrostatics and the Dielectric Circuit; Alternating-current Circuits; Transients; Conduction of Electricity in Solids and Fluids; by Charles Weyl and Irven Travis.
9. RADIATION AND LIGHT: Theory of Radiation; Geometry of Radiation; Physics of Radiation; Physiology of Radiation; by Ernst Weber. ACOUSTICS; by R. B. Lindsay. METEOROLOGY; by Edgar W. Woolard, R. J. Martin, and H. L. Dryden.
10. CHEMISTRY: General Chemistry; Industrial Chemistry; Qualitative Analysis; Electrochemistry; by Joseph Mattiello and Sidney B. Tuwiner.
11. METALLIC MATERIALS: Corrosion of Metals; by Frank N. Speller. Iron and Steel; by Bradley Stoughton. Copper and Copper-base Alloys; by members of the staff of the American Brass Co. and W. M. Corse. Zinc and Zinc-base Alloys; by W. M. Peirce. Aluminum and Aluminum Alloys; by Junius D. Edwards and Zay Jeffries. Nickel and Non-ferrous Nickel Alloys; by Robert Worthington. Magnesium and Magnesium Alloys; by John A. Gann. Tungsten; Molybdenum; by Zay Jeffries. Die-casting Alloys; by J. C. Fox. Bearing Metals; by Christopher H. Bierbaum. Welding, Brazing, and Soldering Materials; by Bradley Stoughton and D. F. Miner. Electrical Conductor Materials; by H. C. Knutson and D. F. Miner. Magnetic Materials, by J. B. Seastone. Miscellaneous Materials.
12. NON-METALLIC MATERIALS: Cement, Concrete, Lime, Mortar, and Plaster; by Theodore Crane. Stone, Brick, and Terra-cotta; by Jasper O. Draffin. Refractories; by J. Spotts McDowell and E. B. Guenther. Thermal Insulating Materials. Timber; by H. C. Knutson and H. F. Moore. Paints, Enamels, Varnishes, and Lacquers; by Joseph Mattiello. Electric Insulating Materials; Lubricants; Adhesive Materials; by D. F. Miner. Fuels and Explosives. Miscellaneous Materials.
13. CONTRACTS. By R. L. Sackett.

# MECHANICAL ENGINEERS' HANDBOOK

## POWER

Edited by Robert Thurston Kent

1226 Pages

SECTION

1. AIR: Properties of Air. Compressed Air, by Robert Peele. Fans and Blowers, by Robert T. Kent.
2. WATER: Properties of Water. Hydraulics, by William P. Creager. Hydraulic Turbines, by R. E. V. Sharp. Pumps and Pumping Engines, by Robert T. Kent. Centrifugal Pumps, by V. deP. Gerbereux.
3. HEAT: Measurement of Heat. Heat Transmission, by W. J. King. Evaporators and Evaporation, by W. L. Badger. Dryers and Drying, by Francis E. Finch. Kiln Drying of Lumber, by L. V. Teesdale. Heat Insulation, by P. Nicholls. Thermodynamics, by A. G. Christie.
4. COMBUSTION AND FUELS: Combustion and Solid Fuels, by Robert T. Kent. Liquid Fuels, by Harry L. Tapp. Gaseous Fuels. Illuminating Gas, by Alfred E. Forstall.
5. STEAM: Properties of Steam; The Mollier Diagram, by A. G. Christie. Flow of Steam in Pipes, by Robert K. Behr. Steam Piping. Stresses in Pipe Lines, by A. S. McCormick. Commercial Pipe and Fittings. Steam Valves.
6. THE STEAM BOILER: Boiler Construction; Superheaters, Economizers and Air Heaters; Utilization of Waste Heat; Moisture in Steam. Boiler Feeding. Feedwater for Steam Boilers. By D. S. Jacobus, Robert K. Behr and Robert T. Kent. Boiler Furnaces; Stokers; Gas and Oil Burners, by W. S. Carter. Chimneys and Draft. Smoke.
7. THE STEAM ENGINE: Capacity of Engines; By W. Trinks. Compound and Triple-expansion Engines; Steam Engine Economy; Operation of Engines; Valve Gears; Operating Data; Steam Engine Parts; Selection of Type of Engine; Cost of Engines.
8. THE STEAM TURBINE: By A. G. Christie. Types of Turbines. Steam Turbine Cycles. Nozzles. Blading. Steam Supply. Rotors. Turbine Details. Reduction Gearing. Lubrication. Turbine Governors. Casings. Erection and Operation. Correction Factors. Turbine Performance. Turbine Calculations. Reheating Turbines. Economic Selection of Operating Conditions. Mercury Turbines.
9. CONDENSING AND COOLING EQUIPMENT: By Robert T. Kent. Direct Contact Condensers. Properties of Saturated Steam below Atmospheric Pressure. Surface Condensers. Air Pumps. Cooling Towers. Cooling Ponds.
10. REFRIGERATION AND ICE MAKING: By Louis A. Harding. Refrigeration. Cold Storage. Heat Transmission. The Ammonia Absorption Machine. Vapor Condensers. Brine Circulating System. Ice Manufacture.
11. HEATING, VENTILATING AND AIR CONDITIONING: By Louis A. Harding. Estimating Heating Requirements of Buildings. Heating Systems. Rating of Heating Boilers. Design of Air Ducts. Ventilation. Air Conditioning.
12. INTERNAL COMBUSTION ENGINES: Diesel Engines, by E. J. Kates. Gas Engines, by H. A. Gehres. Gasoline Engines.
13. GAS PRODUCERS: By John Blizard. General Design and Operation of Gas Producers. Properties of Producer Gas. Design of Furnaces for Producer Gas.
14. TRANSPORTATION: Railroad Engineering, by G. E. Rhoads. Automotive Vehicles, by Ralph A. Richardson. Aeronautics, by Edward P. Warner and S. Paul Johnston.
15. ELECTRIC POWER: By E. S. Dibble. Purchased Power. Generated Power. Conversion Equipment. Switchboard Equipment. Batteries. Power Factor. Power Distribution.
16. POWER TEST CODES: Instruments and Apparatus. Test Codes.
17. MATHEMATICAL TABLES.

# MECHANICAL ENGINEERS' HANDBOOK

## DESIGN. SHOP PRACTICE

Edited by Robert Thurston Kent

1378 Pages

SECTION

1. GENERAL PROPERTIES OF MATERIALS.
2. IRON AND STEEL: Iron and Steel, by Bradley Stoughton. Ingot Iron, by R. L. Kenyon. Welding of Iron and Steel, by J. C. Hodge and R. E. Hiller.
3. CORROSION AND CORROSION-RESISTANT METALS: Corrosion of Metals, by Frank N. Speller. Corrosion-resistant Metals, by Robert T. Kent.
4. NON-FERROUS METALS AND ALLOYS: General Properties of Metals and Alloys, by Paul D. Merica and Norman B. Pilling. Copper, by W. H. Bassett (deceased). Zinc and Its Alloys, by W. M. Peirce. Brass and Bronze Sand-cast, Copper-base Alloys, by W. M. Corse. Wrought Brasses, Bronzes and Nickel-silver Alloys, by W. H. Bassett (deceased), H. G. Jennison, and W. R. Hibbard. Aluminum and Its Alloys, by Zay Jeffries. Nickel and Its Non-ferrous Alloys, by Robert Worthington. Magnesium and Its Alloys, by John A. Gann. Tungsten and Molybdenum, by Zay Jeffries. Die-casting Alloys, by J. C. Fox. Bearing Metals, by Christopher H. Bierbaum. Solders.
5. NON-METALLIC MATERIALS: Refractories, by J. Spotts McDowell. Wood, Cork, Rubber, Carbon and Miscellaneous Materials.
6. FABRICATED MATERIALS: By Robert T. Kent. Plates, Sheets, Bars, Rods and Shapes. Steel, Copper and other Wires. Ropes, Chains, and Wire Rope. Rivets, Nails and Washers.
7. STRENGTH OF MATERIALS: By Edward R. Kent and Jasper O. Draffin. Simple Stresses. Beams. Columns. Shafts. Cylinders, Plates and Rollers. Testing of Materials.
8. MECHANISM AND MECHANICS: By Robert T. Kent. Elements of Machines. Mechanics. Friction.
9. FASTENINGS: By Robert T. Kent. Screws and Screw Fastenings. Rivets and Riveted Fastenings. Fastenings for Timber Joints.
10. MECHANICAL SPRINGS: By Mortimer F. Sayre.
11. ROTATING MEMBERS: By Robert T. Kent. Axles and Shafts. Cranks and Crank-pins. Fly-wheels.
12. KEYS, COTTERS, PINS, TAPERS AND FITS: By Robert T. Kent.
13. BEARINGS AND LUBRICANTS: Oil Film Bearings, by H. A. S. Howarth. Ball Bearings, by J. S. Tawresey. Roller Bearings, by Robert T. Kent. Lubricants, by J. C. Geniesse.
14. GEARING: By Earle Buckingham. Friction Gearing. Spur Gears. Helical Gears. Bevel Gearing. Screw Gearing. Spiral Gear Drives. Worm Gear Drives.
15. CONTROL MECHANISMS: Governing, Regulation and Control, by W. Trinks. Brakes, by Robert T. Kent.
16. VIBRATION AND NOISE: By Arthur L. Kimball.
17. STRUCTURES AND BUILDINGS: Stresses in Framed Structures. Building Construction, by Theodore Crane. Properties of Structural Materials, by Robert T. Kent.
18. INDUSTRIAL HEATING PROCESSES: Industrial Furnaces, by W. Trinks. Industrial Electric Heating, by R. M. Cherry.
19. FORGING PRACTICE: By Eugene C. Clarke.
20. FOUNDRY PRACTICE: Iron Foundry Practice, by D. M. Avey. Malleable Castings, by Enrique Touceda. Non-ferrous Foundry Practice, by N. K. B. Patch.
21. THE MACHINE SHOP: Lathe Work. Single-point Metal-Cutting Tools, by Robert C. Deale. Planer Work, by Forrest E. Cardullo. Pressure Working of Metals, by H. B. Morse. Drills and Drilling; Abrasive Processes; Broaching; Metal Sawing; Machine Tool Motor Drives; Measurements, by Robert T. Kent.
22. WOODWORKING: By Thomas D. Perry. Materials. Primary Conversion Machinery. Processing. Small Tools. Machine Tools for Wood.
23. MATERIALS HANDLING: By Frederic V. Hetzel. Hoisting. Handling Materials in Bulk. Cranes and Derricks. Hoists. General Conveying and Elevating. Belt Conveyors. Screw Conveyors. Pneumatic and Hydraulic Conveying. Package Handling. Vehicles. Manufacturers of Material Handling Equipment.
24. MECHANICAL POWER TRANSMISSION: By Robert T. Kent. Shafting. Pulleys. Belt Drives. Chain Drives. Rope Driving. Couplings and Clutches. Speed Changing Mechanisms. Dynamometers.
25. ELECTRIC MOTORS AND THEIR CONTROL: By M. N. Halberg. Electric Motors. Electric Motor Control.
26. MISCELLANEOUS SHOP EQUIPMENT: Dust Collection, by M. S. Kice, Jr. Illumination, by Matthew Luckiesh.
27. SAFETY ENGINEERING: By Sidney J. Williams. Accident Prevention. Mechanical Power Transmission. Machinery. Electrical Hazards. Eye Protection and Safe Clothing. First Aid. Supervision and Education. Organizations.
28. MATHEMATICAL TABLES.

# HANDBOOK FOR ELECTRICAL ENGINEERS

## ELECTRIC POWER

Edited by Harold Pender, William A. Del Mar, and Knox McIlwain

1300 Pages

SECTION

1. MATHEMATICS, UNITS, AND SYMBOLS: Mathematics; by Carl C. Chambers. Mathematical Tables. Units and Conversion Factors; by J. G. Brainerd and Carl C. Chambers. Symbols and Abbreviations. Constants; by Carl C. Chambers.
2. PROPERTIES OF MATERIALS: Weights of Materials; Conductor Materials; Insulating Materials; Magnetic Materials; Thermal Properties of Materials; by D. F. Miner.
3. ELECTRIC CIRCUITS AND ELECTRIC LINES: Alternating Currents; Linear Circuits; Non-linear Circuits; Polyphase Systems and Symmetrical Components; Electrical Machines; Transmission Lines; Stability of Power Systems; by Irven Travis.
4. RESISTORS, REACTORS, MAGNETS: Resistors, Rheostats; Capacitors—Condensers; Inductors; Magnets, Magnetic Devices; by A. Dexter Hinckley.
5. MEASUREMENTS AND MEASURING APPARATUS: by H. B. Brooks.
6. PRINCIPLES OF ELECTROCHEMISTRY: by H. M. Goodwin, revised by Martin Kilpatrick and Mary L. Kilpatrick.
7. BATTERIES: Primary Batteries; by C. F. Burgess. Lead-acid Storage Batteries; by J. Lester Woodbridge. Alkaline-type Storage Batteries; by E. W. Allen and F. Brehme.
8. DIRECT-CURRENT MACHINES: Direct-current Generators; Direct-current Motors; by Walter I. Slichter.
9. ALTERNATING-CURRENT MACHINES: Alternating-current Generators; Synchronous Motors; Polyphase Induction Motors; Single-phase Induction Motors; Alternating-current Commutator Motors; by Walter I. Slichter.
10. TRANSFORMERS; by Walter I. Slichter.
11. CONVERTERS AND RECTIFIERS: Energy Converters; Frequency Converters; Phase Converters and Balancers; Rectifiers; by Walter I. Slichter.
12. SWITCHING, CONTROL, AND PROTECTION: Circuit Elements; Circuit Breakers; Controllers and Regulators; Protection; Station Equipment; Station Structures and Layout; by Stephen Q. Hayes.
13. POWER STATIONS AND SUBSTATIONS: Steam Power Stations; by F. S. Bennett. Hydroelectric Power Stations; by R. A. Hopkins and A. G. Cherry. Internal-combustion Power Stations; by W. A. Sloan. Substations; by W. I. Slichter. Power Station Circuits; by R. A. Hopkins.
14. POWER TRANSMISSION AND DISTRIBUTION: Systems; Capacitance and Inductance Tables; Underground Conduits; Distribution; Bare Wires and Cables; Insulated Wires and Cables; Electrolysis of Underground Structures; by W. A. Del Mar. Electrical Design of Transmission and Distribution Systems; by W. A. Del Mar, J. H. Palmer, F. W. Peek, and R. A. Philip. Pole and Tower Lines; by Howard Enos. Wiring of Buildings; by G. W. Zink. Grounding of Electric Circuits and Accessories; by R. F. Abele.
15. LIGHTING AND HEATING: Lighting; by F. C. Caldwell. Household Heating Appliances and Cooking; by Frank Thornton, Jr. Water Heating; by C. J. Fay and J. F. Reifenberg. Heating and Air Conditioning of Buildings; by Otto W. Walter.
16. INDUSTRIAL APPLICATIONS OF MOTORS; by Francis A. Westbrook.
17. TRANSPORTATION: Electric Traction; by H. A. Currie and Robert S. Rhodes. Electrical Equipment of Internal-combustion Automobiles; by H. Chase. Electric Automobiles; by W. P. Kennedy. Electric Propulsion of Ships; by W. N. Zippler.
18. ELECTROCHEMICAL AND ELECTROTHERMAL INDUSTRIES: Electrochemical Processes; Electric Furnaces and Their Products; by M. de K. Thompson. Electric Resistance Heating; by Frank Thornton. Jr. Electrical Precipitation of Suspended Particles; by N. W. Sultzer. Electric Welding; by H. M. Hobart.
19. ELECTRICITY ON THE FARM; by Lee C. Prickett.

## HANDBOOK FOR ELECTRICAL ENGINEERS

## COMMUNICATION. ELECTRONICS

Edited by Harold Pender and Knox McIlwain. 1022 Pages

SECTION

1. MATHEMATICS, UNITS, AND SYMBOLS: Mathematics; by Carl C. Chambers. Mathematical Tables. Units and Conversion Factors; by J. G. Brainerd and Carl C. Chambers. Symbols and Abbreviations. Constants; by Carl C. Chambers.
2. PROPERTIES OF MATERIALS: Conducting Materials; Insulating Materials; Luminescent Materials; Magnetic Materials; Special Properties of Dielectrics; by William F. Diehl with W. R. Dohan, H. W. Leverenz, D. G. C. Luck, and C. R. Nelson.
3. ELECTRIC CIRCUITS, LINES, AND FIELDS: Linear Electric Circuits; General Network Theory; Recurrent Networks; Non-linear Electric Circuits; Electromagnetic Radiation; Electromechanical Systems; by Knox McIlwain.
4. RESISTORS, INDUCTORS, CAPACITORS: Resistors and Rheostats; Inductors with Air Cores; Ferrous-cored Inductors; Capacitors, Condensers; by A. Dexter Hinckley.
5. ELECTRON TUBES: Thermionic Vacuum Tubes; by B. J. Thompson with J. M. Stinchfield, Bernard Salzberg, and E. W. Herold. Gaseous Conduction Tubes; by O. W. Livingston. Cathode-ray Oscillograph Tubes; by G. F. Metcalf. X-ray Tubes; by S. Reid Warren, Jr. Photoresponsive Devices; by H. E. Ives.
6. ELECTROMECHANICAL-ACOUSTIC DEVICES: Effects of the Acoustic Medium; Loud Speakers and Telephone Receivers; Microphones; by Hugh S. Knowles. Mechanical Recording and Reproducing of Sound; Optical Recording and Reproducing; Magnetic Recording and Reproducing; by H. A. Frederick and A. C. Keller.
7. CIRCUIT ELEMENTS: Single Mesh and Coupled Circuits; by Vernon D. Landon and Knox McIlwain. Transformers with Iron Cores; by J. I. Cornell and A. J. Rohner. Electrical Wave Filters; by T. E. Shea and C. E. Lane. Radio Antennas; by G. C. Southworth. Vacuum-tube Amplifiers; by Loy E. Barton. Modulators; Power Supply; Radio Transmitters; by J. E. Young. Detectors; Radio Receivers; by Vernon D. Landon. Oscillators; by Carl C. Chambers.
8. HIGH-FREQUENCY TRANSMISSION: Wire Transmission Lines; by Knox McIlwain. Transmission in Space; by John C. Schelleng. Mechanical Features of Transmission Lines; by C. H. MacDonald. Coordination of Communication and Power Systems; by C. H. MacDonald and H. A. Dambly.
9. ACOUSTICS: The Sense of Hearing; Speech and Music; Effects of Distortion on Speech and Music; by John C. Steinberg. Acoustic Properties of Rooms; Sound Insulation; Acoustic Design of Auditoriums; by Vern O. Knudsen.
10. ELECTRICAL MEASUREMENTS: Frequency Measurements; by W. A. Marrison. Measurement of Primary Electrical Quantities; by W. J. Shackelton and J. G. Ferguson. Wire Transmission Measurements; by F. H. Best. Measurements of Transmission through Space; by R. K. Potter. Wave Analysis; by E. Peterson and T. G. Castner.
11. TELEGRAPHY: Elements of Telegraph Systems; D-c Telegraph Systems; A-c Telegraph Systems; Printing Telegraph Systems; Local Equipment; Submarine Cable Telegraphy; by Allison A. Clokey. Radio Telegraph Systems; by J. L. Finch.
12. SOUND-REPRODUCTION SYSTEMS: Acousto-electric Equipment; Radio Telephone Broadcasting; by Howard A. Chinn. Electro-acoustic Equipment; by W. H. Bohlke and Knox McIlwain. Public Address Systems; Sound Pictures; by Knox McIlwain. Police Radio Systems; by Loren F. Jones.
13. TELEPHONY: Substation Equipment and Circuits; Central Office Systems; by Knox McIlwain. Telephone Lines; by C. H. MacDonald. Radio Telephone Systems; by A. A. Oswald.
14. FACSIMILE TRANSMISSION AND RECEPTION: Scanning Systems; Recording Systems; Transmission and Synchronization; Complete Facsimile Systems; by Maurice Artzt.
15. TELEVISION: Transmitting Point Analyzer; Transmission Channel; Receiving Point Reproducer; Scanning Systems (Electrical); Complete Television Systems; Circuit Elements Peculiar to Television Systems; by H. Branson and R. L. Campbell.
16. ELECTRONIC CONTROL AND NAVIGATION EQUIPMENT: Fundamental Electronic Control Circuits; Light-sensitive Control Equipment; Thyratron Control Equipment; by W. R. King. Radio Aids to Air and Marine Navigation; by W. E. Jackson and J. C. Hromada.
17. MEDICAL APPLICATIONS OF ELECTRICITY: Electrotherapy; Diathermy and High-frequency Surgery; Ultra-violet-ray Therapy; Physiological Electromotive Forces; Electro-acoustic Devices; Roentgen Therapy; Roentgenography and Roentgenoscopy; High-voltage Shock and X-ray Burn; by Charles Weyl.

# OTHER WILEY HANDBOOKS

## THE ENGINEERS' MANUAL

By RALPH G. HUDSON, assisted by the late JOSEPH LIPKA, DEAN PEABODY, and HOWARD B. LUTHER. Second edition. 340 pages. 5 by 7¾. 227 figures. Flexible binding.

## ARCHITECTS' AND BUILDERS' HANDBOOK

By the late FRANK E. KIDDER. HARRY PARKER, Editor-in-chief, with the collaboration of a staff of 18 specialists. 18th edition. 2315 pages. 4½ by 7. Flexible binding.

## MERRIMAN'S AMERICAN CIVIL ENGINEERS' HANDBOOK

THADDEUS MERRIMAN, the late Editor-in-chief; THOMAS H. WIGGIN, Associate Editor-in-chief; with a staff of 21 specialists. Fifth revised edition. 2263 pages. 4¼ by 7. One volume, atholeather; two volumes, real leather.

## MINING ENGINEERS' HANDBOOK

ROBERT PEELE, Editor-in-chief. Second edition. 2523 pages. 4½ by 7. Flexible binding. Two volumes, real leather.

## HANDBOOK OF ORE DRESSING

By ARTHUR F. TAGGART and 7 contributors. 1679 pages. 5 by 7¾. Flexible binding.

## VEST-POCKET HANDBOOK OF MATHEMATICS FOR ENGINEERS

By the late L. A. WATERBURY with special sections by the late G. A. GOODENOUGH and H. H. HIGBIE. Third edition, enlarged. 278 pages. 3 by 5½. Flexible binding.
